MISCELLA 496 100 years ago 562 Erratum 569 **Books Received** 570 **Announcements** ix New on the market

Classified advertising

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed stems (figures plus tables). A draft abstract (50 words) is required.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

K.G. Denbigh Three Concepts of Time

1981. Approx. 180 pages. DM 39,—; approx. US\$18.60 ISBN 3-540-10757-6 Price is subject to change without notice

Contents: Time as a Many-Tiered Construct: The Porblem Situation. The Objectivity 1 of Time. The Objectivity2 of Time. The Problem of 'The Present'. - Temporal Processes: The Interplay of Chance and Causality. Thermodynamics and the Temporal Asymmetries. Temporal Ongoings in Biology. Time and Consciousness. – References. - Subject Index.

This broad discussion of "time" and its empirical and scientific aspects was written to make the subject interesting and accessible to awide audience.

The author shows that "time" is a composite notion having several different sources and that, consequently, there are three distinct concepts of

- the time of theoretical physics
- the time of thermodynamics and of the evolutionary sciences such as biology
- the time of conscious awareness.

The book traces the differences and similarities between these three concepts and their relative fields of application. Much attention is given to the nature of temporal ongoings in the universe. to the coming into being of genuinely new things during "the course of time" and to the linking up of time with issues in biology and with the mind/ body problem.

Although the author emphasizes the ideas of modern philosophy, a background in philosophy is not a prerequisite. The book's distinctive approach - viewing time as neither a purely physical nor a purely mental concept, but partaking of both - will enable readers to confront the strange puzzles and paradoxes of time from a much wider viewpoint than is presented in most other texts.

Can cancer at work be regulated?

In the century and a half since cancer of the scrotum among chimney sweeps was first recognized as an occupational disease, interest in (and anxiety about) occupational cancer has grown steadily. Since the Second World War, there has been continuing concern for the health of those occupationally exposed to ionizing radiation, and all governments have introduced regulations intended to limit the exposure of workpeople and thus the risk of overt disease. More recently, attention has turned to the occupational risks of the exposure of workpeople (and also the general population) to industrial chemicals. In the United States, the passage of the Occupational Health and Safety at Work Act in 1970 led to the creation of two separate organizations with responsibility in the field - the National Institute for Occupational Safety and Health (whose function is research and evaluation) and the Occupational Safety and Health Administration (which can regulate industrial practice). In Britain, legislation on the American model led in 1974 to the creation of the Health and Safety Executive and its supervisory commission. For the past three years, the Health and Safety Executive has been struggling with a regulation requiring the notification of new chemical substances (see Nature 16 July, p.190) but even now is unlikely to meet the deadline of 18 September decreed by the European Commission.

Nobody should be surprised. European administrations' attempts to restrict the introduction of potentially hazardous chemicals are the analogues of the regulations enshrined in the Toxic Substances Control Act of 1976, which took the best part of six years to emerge from an embattled Congress in the United States. There are several contentious issues. Chemical companies resent the cost of subjecting all new chemicals to a battery of short and long-term toxicity tests - and, with more reason, fear that too wooden an exercise of regulatory powers by the responsible agencies may deprive them of the use of a valuable intermediate even when effective precautions may be taken. A more serious difficulty, shown up by the muddled division of responsibility in the United States between the Environmental Protection Agency (responsible for the administration of the Toxic Substances Control Act) and the Occupational Safety and Health Administration is that of making sensible arrangements for the protection of the public at large, and of people occupationally exposed to larger concentrations of the same materials.

In Britain, as earlier in the United States, a further complication has arisen — the interest of the trades unions in the design of the regulations and in their administration. This development is entirely to be welcomed. Even the most diehard opponents of organized labour would agree that unions are better occupied in the protection of the health of their members than in some of the other things they do. Industry as a whole, and the community at large, can only benefit from a proper understanding by its workpeople of the occupational risks they are asked to run — and from their informed consent that risks of some magnitude, ideally small but probably not identical with zero, should be run. The time that might now be spent in Britain by the Health and Safety Executive on reconciling the interests of the trades unions and the chemical manufacturers would be well worthwhile.

Unfortunately, good sense is in danger of being overtaken by events. The Health and Safety Executive, applauded ever since its creation as a novel and autonomous entity within the British constitution, is much in need of the safety valve of which its special place deprives it — an expression of a range of prejudiced

opinion in the House of Commons. (Is the House of Lords too busy to oblige?) The second draft of its regulations on the notification of new substances is indeed needlessly onerous, too cut and dried, and the executive should take the time to produce a third, whatever they say in Brussels. The trouble, now, is that the executive has to watch out not only for the European Commission but for Mr Clive Jenkins, the secretary of the trade union called the Association of Scientific, Technical and Managerial Staffs.

Mr Jenkins's union has in the past few years taken a close and often constructive interest in problems of occupational health and safety. More than a year ago, it produced an arresting (if controversial) document about the occupational hazards of new chemicals. Ten days ago, Mr Jenkins issued a lengthy commentary on the second draft of the Health and Safety Executive's proposed notification regulations and made some cogent points. Chemical companies are indeed too defensive of their superficial financial interests, and too unwilling to let independent outsiders enquire into their affairs. The costs of complying with regulations have been systematically (that is, consistently) exaggerated. And so on. He erred only in the most rudimentary way — by supposing that there is some state of grace in which occupational risks are absolutely avoidable. His problem, and the executive's, is rather how to strike a balance between the possibly carcinogenic risk of a novel chemical and the possibility that somebody, or some group, will be out of work. Who will persuade whom of that?

Damming estuaries

The hope that there might be some other way — any other way - of generating electricity than those now used is likely to be widely paraded in the weeks ahead. The United Nations conference on alternative energy sources due to open in Nairobi next week will be an obvious forum (see also page xxx). And nobody should deride the innocent declarations of faith in windmills, water-wheels or wood (now called biomass) that there will be. There are unfortunately still too many circumstances, in still too many developing countries, in which any way of generating a modicum of mechanical power from some indigenous source is much needed. But those who assemble in Nairobi should also take to heart the message hidden in last week's report of Sir Hermann Bondi's study of the feasibility of an electricity-generating barrage across the Severn estuary, between England and Wales (see Nature 30 July, p.401). The conclusion of this thorough piece of work is that if British taxpayers want the kinds of benefits that a barrage across the Severn estuary would provide, they would be best advised to build nuclear power stations and not a dam.

The argument is simple but instructive. A dam across an estuary can be used to generate electricity in several obvious ways — by letting the incoming tide drive turbines in a dam, by letting water impounded at high tide run back through turbines on the ebb tide or (as in the scheme operated by Electricité de France on the estuary of the Rance since 1966) arranging that water in an estuary will drive turbines at both the ebb and flood tides. The amounts of energy that can in principle be won from such schemes are huge—the Bondi committee estimated that even the most modest of all possible dams across the Severn could yield 13 TWh of electricity, something like six per cent of present electricity demand in the United Kingdom, roughly the amount of electricity that would be

generated by the use of 7 million tons of coal a year, year in and year out. The snag is that not a single kilowatt-hour of this electricity would accrue until the whole dam across the Severn estuary had been built — a process likely to take 15 years and to cost £5,660 million without allowing for the cost of paying interest on this substantial sum of money while construction is under way. But is not any scheme that produces energy from a renewable resource, such as the slopping one way and another of water in a tidal estuary, inherently worthwhile? That is what the enthusiasts for the Severn barrage have been saying almost since the beginning of the electricity supply industry itself. Unfortunately, a careful reading of the Bondi committee's first report shows the argument to be false.

As in other industrially developed countries, the British demand for electricity is a reasonably well-defined function of the time of day and the season of the year. Inevitably, the daily pattern of demand is linked with the movement of the Earth about the Sun and not with the movement of the Moon about the Earth, with the result that maxima of demand coincide only by accident with tidal maxima. Similarly, seasonal variations bear no constant relationship to the occurrence of spring or neap tides, which are related to the relative alignment as seen from the Earth of the Sun and the Moon. None of this is surprising. The consequence is, however, that a dam across the Severn would be capable of generating electricity at times only randomly related to those at which electricity demand is greatest. Accordingly a Severn barrage (or any other tidal scheme for generating electricity) will not substantially reduce the need for building other kinds of generating plant to satisfy the maximum demand on the system. (This blunt statement is a little over-gloomy, for electricity utilities would in principle be able to plan routine maintenance of conventional plant on a lunar calendar and thus obviate the need for some capital investment.) Such benefits as there are from tidal schemes, however, consist only in the avoidance of fuel costs at conventional power stations, some of which may be shut down when barrage schemes are ready to generate electricity. Overall, the crucial question is whether, over the lifetime of a barrage, the initial capital cost will be justified by the conventional fuel (coal, oil and uranium) that would be saved.

The Bondi committee, which includes several enthusiasts for big dams, puts a brave face on this daunting prospect. On the basis of a calculation of the present value of the conventional fuel that a Severn barrage would save, it concludes that the most modest version of such a scheme would just about pay for itself. There will be much technical interest in the way in which this calculation has been carried out — and curiosity will be satisfied only when the full report of the study is published two months or so from now. Already, however, it is clear than even this calculation is over-optimistic. The committee has assumed in calculating costs and benefits that the annual rate of interest on capital is either 5 per cent or 7 per cent — much less than the cost of the money the British government is having to borrow to finance less ambitious projects than the Severn barrage. But that is only half the story. The Bondi committee, with its hand firmly on its heart, makes the honest declaration that the economic benefits of investing in nuclear power stations would be roughly twice those of investing in the Severn barrage.

None of this implies that schemes for the exploitation of renewable energy should not be examined. The Bondi study is a model of how such exercises should be carried out. But enthusiasts for the use of renewable energy resources should acknowledge that conclusions such as those that have now put paid to dreams of a barrage across the Severn are likely to afflict many other projects for generating electricity in unconventional ways. After all, the properties of a stream of electrons in an electrical conductor are independent of the source of the electrical potential that drives them. By making uneconomic judgements about the virtues of different sources, it is possible to waste vast amounts of wealth that might be used in other ways. This is not to say that the United Nations conference at Nairobi should promptly adjourn, and amalgamate with the meeting of the major electricity utilities at the next World Power Conference, for there

is much that might be done by a sober appraisal of small power sources for use in places where there is hardly any power of any kind available at present. But, in the long run, the hard economics that have ruled out the Severn barrage in Britain are likely also to apply elsewhere.

Cricket and patriotism

The British, much depressed for several years by problems in Ulster and of economic misjudgement and mismanagement, have been so curiously uplifted in the past few weeks by a royal wedding and their success in beating the Australians twice at cricket that the question must be faced whether the psychological benefits of these public spectacles can be more widely spread. For if there is the slightest chance that peoples elsewhere might be given the courage to face intractable problems — or perhaps even the excuse to forget about them for a time - by a suitable patriotic display, should not governments other than the British be ready with plans for suitable ceremonies? Precedents set by the Roman emperors, however politically prudent 2,000 years ago, would no longer be acceptable, while the chances are small that governments will value royal weddings so highly that they would embark on the constitutional upheavals necessary to introduce monarchies of their own. On the face of things, only the game of cricket is potentially adaptable to other circumstances than the British, and even there the prospects are not bright.

The difficulty with cricket is that it is not widely understood. There is, however, no reason to accept the complaint of those not subjected to an English education that the game is inherently incapable of being understood. The way in which cricket has spread through much of the British Commonwealth gives the lie to this canard; the fact that West Indian cricketers are probably now more skilled than any others is a sign that cricket could become an international vehicle for national contentment, even chauvinism. To that end, the most urgent need is for a deeper understanding of what cricket is about. It may even be necessary to simplify the rules.

The fundamental principles of cricket are by no means unique. As in baseball, one person throws a ball at another, who is equipped for his defence with a piece of wood called a bat. Superficially, cricket is more objective than baseball in that a batsman's defence is held to have been unsuccessful if the ball strikes one of three pieces of wood planted on the ground behind him, and not merely on the say-so of an umpire who has to judge whether the ball passes at the right height over an object laid in the ground. What puzzles potential devotees of cricket is that the ballthrowing act is routinely performed in each of two opposing directions and that there appears to be no limit to the number of people who can be invited to throw the ball. It is also puzzling to many that ball-throwers (called "bowlers") may legitimately bounce their projectiles on the ground in front of the hapless batsmen, thus introducing an element of disconcerting randomness into their trajectories.

Fortunately, these faults are easily remediable. One-ended cricket played on an adhesive surface (so that cricket balls could not be bounced) would plainly make it possible for others than the Old Commonwealth to understand and thus to enjoy a game to which they are at present denied access. The time taken by cricket matches could be reduced if batsmen were given less substantial pieces of wood. For obvious economic reasons, it would be necessary to reduce the duration of international matches from five days to five hours, which to a first approximation would require that the presenting surface of the standard bat should be reduced by approximately five-sixths. The disadvantage that it would then be difficult for batsmen to accumulate large individual scores - one of the prerequisites of national cricket heroes — could be offset by multiplying by six the present rewards for batsmanship. No doubt there would be many in places where cricket is understood who would resist these innovations. But should tradition be allowed to stand in the way of a wider distribution of the benefits that cricket might bring?

Stanford sells gene-splicing licences

Boyer, Cohen patent may yet be challenged

Washington

In a move expected to bring in annual royalty payments of over a million dollars within the next four or five years, Stanford University announced this week the terms under which it is prepared to let commercial companies use the genesplicing techniques developed in the early 1970s by Dr Stanley Cohen of the university's medical school and Dr Herbert Boyer of the University of California in San Francisco.

The techniques have since become the basic tools for many widely used genetic engineering processes. University researchers who wish to use them may continue to do so free of charge, but companies marketing products based on their use will be required to pay a royalty fee varying from one per cent of net product sales below \$5 million to 0.5 per cent on annual sales of over \$10 million.

Before reaching the commercial stage, any company wishing to use the techniques in its research can purchase a non-exclusive licence from Stanford for an initial fee of \$10,000, and an annual sum of the same amount. An incentive offered to those who act quickly is that any company which signs up before the end of 1982 can credit five times the licence fee against future royalties, up to a maximum of 50 per cent of the royalties earned in any one year.

Stanford will deduct 15 per cent from fees and royalties earned to servicing the licensing arrangements. After that the remaining sum will be divided equally between Stanford and the University of California. Stanford's share will be further divided, with a third going to the university's medical school and a third to its departments of medicine and genetics. Dr Cohen, who holds joint appointments in the two departments and who would under the university's normal rules be entitled to the remaining third, has assigned his share back to the university, to be divided between biomedical research and support for postdoctoral fellowships. Dr Boyer has also waived any rights to personal royalties.

Despite being one of the leading research universities in the United States, with an annual research budget of over \$100 million, Stanford has so far lacked any major money-spinning patents comparable, for example, with the widely-used dental fluoride developed at the University of Indiana. University officials are hoping that the income from the patent on the Cohen/Boyer techniques, filed in

1974 and granted last December, will change this, although president Donald Kennedy says he does not anticipate that royalty income from this source "will significantly alter our present financial projections".

The patent granted by the Patent Office is broad, covering the series of steps used by Drs Cohen and Boyer to replicate and express exogenous genes in microorganisms. It describes the techniques used to cleave a plasmid or virus DNA, to insert a new gene to provide a biologically functional replicon, to place the latter in a microorganism cell, and finally to isolate the transformants in order to produce cells in which the DNA molecules in the modified plasmid can be replicated and expressed.

The breadth of the patent — and the ubiquity of the techniques' current usage — means the university is expecting a large number of licensing requests. In a statement issued on Monday it estimated that more than 200 companies in the United States may already be involved, and that half may sign up for the licences in the near future.

At the same time, this breadth could lay the patent open to challenge from other scientists who claim to have made significant contributions to the results which were patented by the universities solely in the names of Cohen and Boyer. Murmurs of possible legal challenges have surfaced in the past, although the relatively low licence fee — as well as the fact that the royalties will go to the universities and not to the individual scientists — may well dampen any conflict.

Stanford is requiring that any company obtaining a licence must agree to use the techniques in compliance with the guidelines for physical and biological containment of experiments drawn up by the National Institutes of Health.

The university has also welcomed a recent ruling by the International Trade Commission forbidding the unlicensed import of goods made abroad with techniques patented in the United States. Previously it had been feared that companies might try to avoid the licensing fee and royalty payments by setting up production facilities in other countries.

David Dickson

Chevènement wins control of science

France's civil science is now almost totally in the hands of one man, Jeane-Pierre Chevenment, the left-wing minister of state for research and technology (see *Nature* 2 July, p.3).

Chevènement has been battling for weeks with other ministers — notably two successive ministers of industry — for the power he believes he needs to direct France's scientific future. Now he has won.

A decree published last week gives him control of the budget for all government-funded civil research, development and technology. The budgets of all public bodies concerned with such matters will henceforth be ascribed to his ministry, giving him around FF20,000 million (£2,000 million) to play with each year.

Nevertheless, the formula which gives Chevenement these powers is complicated, and is likely to be read very closely by all concerned.

Chevènement will, however, have total authority over the Centre National de la Recherche Scientifique (CNRS), which plays the leading role in supporting basic science in France. CNRS has 1,200 laboratories (including a third of all university laboratories) most of them managed jointly with the universities or other institutions but 250 of them completely independent. CNRS is a dominating influence in basic research in France, with the possible exception of mathematics; it has a staff of 25,000, of whom 8,000 are researchers.

Previously CNRS was under the authority of the ministry of universities,

and some now think that the separation from that ministry may complicate the management of joint laboratories: Chevenement is primarily interested in science as the driving force of industrial development, which may not match the views of some university departments. But he has also described science as an essential element of "culture" (music to the ears of President François Mitterrand) and wishes further to improve the international standing of French science.

Other bodies over which Chevenement will have total authority are the Délégation Générale à la Recherche Scientifique et Technique, which will act as his secretariat; the Agence Nationale pour la Valorisation de la Recherche (aimed at turning government-sponsored research into industrial innovations, through venture-capital grants); and two ministerial services, the Mission Interministérielle pour le Développement de l'Information Scientifique et Technique, and the Délégation à l'Innovation et à la Technologie.

Over other organizations, such as the Commissariat à l'Energie Atomique and the Centre National d'Etudes Spatiales, Chevènement will have control through the indirect (but powerful) lever of the budget; and also, if the relevant paragraph in the decree is so interpreted, through appointments.

This paragraph gives Chevenement the task of undertaking "all reform" of public bodies concerned with research, including "all measures have an impact on the

politics of scientific employment" — which he must countersign.

Chevenement will also "be associated with" France's efforts in international scientific cooperation, in cooperation with the foreign minister M. Claude Cheysson.

The decree outlining Chevenement's powers has required negotiation at the highest possible level, and has been signed by President Mitterrand, Prime Minister Pierre Mauroy, the foreign minister and ministers of industry and education.

The national colloquium on science and technology will now take place on 13-16 January 1982, and Chevenement is laving great emphasis on its role in defining a new politics of science in France, and the major "loi-programme" for science which he is to put before parliament next year. The colloquim is to have six principal sessions: on the cultural contribution of science and scientific responsibility; on the internal division of money for science (scientific and technical options, big science and so on); the role of science in helping France to climb out of the recession and create employment; the management of scientists (contracts of employment and so on); the role of other bodies influencing science (big industry, for example); and the political and structural means adopted by Chevènement himself. Robert Walgate

No rapprochement

The usually covertly political nature of education in France came out into the open last week with the sacking of 14 of the 28 regional education officials.

These officials administer education from primary to university level within the "Académies", territories which encompass several of the French departments; ever since General de Gaulle revised their powers in 1967, they have become increasingly political figures. Madame Saunier Seïté, Giscard d'Estaing's minister of universities, was previously head of an Académie; and others became junior ministers or ministerial advisers.

In effect, this was inevitable under de Gaulle's ordinance, which loosened their hold on power and so made them more reliant on the goodwill of the government. Now fourteen unlucky incumbents have been found to be tarred too heavily with the brush of the previous administration, and must go.

This will make room for a "profound reform", the minister of education, M. Alain Savary, said last week in a press statement. The new administrators must not make politics, he said; they must obey the politics of the government. Their predecessors, by contrast, had been active against the new government both before and after the election. Some had stood as candidates for opposition parties. The deposed director of the Paris Académie, for example, had been Saunier Seïté's chief adviser.

Robert Walgate

Alternative energy conference

Realism the theme

Washington

At least five heads of state, including Canadian Prime Minister Pierre Trudeau and Mrs Indira Gandhi of India, will be among the participants at the United Nations Conference on New and Renewable Sources of Energy (UNERG) which starts in Nairobi next Monday. Their presence, together with energy and other ministers of industrialized and developing nations, is held by the conference organizers to indicate a measure of success in getting across their view of the political importance of alternatives to oil, coal, gas and nuclear energy.

But political weight alone will not guarantee a successful conference. UNERG is likely to set a very different tone from the large UN conferences of the 1970s, when global issues such as environmental pollution and the "human habitat" were confronted in a spirit of optimistic idealism.

From the beginning, UNERG has been organized with a more pragmatic outlook. It was, for example, agreed by a narrow vote of the UN General Assembly that nuclear power would not be included on the "new energy technologies" agenda, a move supported by many industrialized nations which feared the result would be too difficult to handle, but opposed by developing nations on the grounds that its exclusion - together with any explicit reference to conventional energy sources - would inevitably skew any results. But perhaps the main stimulus for pragmatism is the general feeling that grandiose schemes for new international bodies (such as the UN Environmental Programme, set up after the Stockholm conference in 1972), or even for a commitment to significant increases in development aid funds, are unlikely to gain support in an international mood of austerity.

In such a context, the tangible achievements of the Nairobi meeting will inevitably be limited. But Secretary General Enrique Iglesias, seconded to direct conference preparations from his permanent position as head of the Economic Commission for Latin America, remains confident that it can still have a real impact by bestowing legitimacy on energy sources frequently omitted from development planning.

One of the most practical parts of the conference has already been completed — a series of technical reports on fourteen different types of new and renewable energy sources, from wind energy to draught animals. The quality of the reports is mixed; but some, such as that produced by an international panel on wind energy, have met with wide approval. And the preparation of national contributions for the conference is said to have catalysed thinking about alternative forms of energy

production and energy planning in general — particularly in some of the developing countries — that had previously been virtually non-existent.

How these will evolve into practical initiatives remains to be seen. Several industrialized countries are said to be keen to support the setting up of research and training institutes for the various energy sources, wood-fuel being the most frequently quoted example. And the Society for International Development is promoting the idea of an international network of energy research institutes along the lines of the agricultural research network run by the World Bank.

The political debate will inevitably focus on the two factors which tend to dominate all international meetings of this nature: money (development aid contributions, primarily from the industrialized nations), and power (the organization of the UN bureaucracy).

Initially the developed and developing nations will be less far apart than at the UN Conference on Science and Technology for Development (UNCSTD) in Vienna in August 1979, where the Group of 77 arrived at the bargaining table with a proposal for a new fund to support Third World research with a budget of \$2,000 to \$4,000 million. This time the developing countries have accepted that such proposals are unrealistic. Any extra support for development of new energy technologies is therefore likely to come from changes in existing arrangements.

The conference organizers originally hoped that the meeting would coincide with the creation of a new "energy affiliate" by the World Bank, a proposal put forward by the bank's then President Robert McNamara last year as a device for raising capital for energy production schemes. So far, though, this has been vetoed by the Reagan Administration on the grounds that investment should, where possible, be left to the private sector.

With the World Bank's initiative stalled — and general agreement that the Nairobi conference should not try to set up a new energy fund — one of the most likely outcomes is an agreement that energy projects should receive a set proportion of the funds raised through a new "financing system" for science and technology, which has been in the planning stages since the Vienna meeting two years ago.

If approved in principle by the General Assembly later this year, the "financing system" would probably take over responsibility for projects at present financed through a two-year interim fund, also established at Vienna, operated by the UN Development Programme. The interim fund already supports several energy projects, such as research into the use of wind power in Mauritius and the introduction of more efficient wood-stoves into the Sahel region of Africa.

To a large extent, however, the most significant meetings will not take place in

Nairobi at all, but will be those surrounding the summit meeting planned for Mexico in October under the auspices of the Brandt Commission. This meeting, which will be attended by President Reagan, is expected to set the tone for negotiations between developed and developing nations for the first half of the 1980s; as a result, it will provide the setting within which any results from Nairobi will inevitably be judged.

David Dickson

To the gulags

The last two members of the Moscow "Working Commission to Investigate the Use of Psychiatry for Political Purposes", Irina Grivnina and Feliks Serebrov, were last month tried and convicted on charges of anti-Soviet activity. Ms Grivnina was sentenced to five years' internal exile, Mr Serebrov to four years in a labour camp plus five years internal exile.

The "Working Commission" was established in 1977 as part of the general human rights monitoring movement in the Soviet Union, and its members made determined efforts to visit "patients" confined in psychiatric hospitals because of their political beliefs. The commission produced a samizdat (information bulletin) giving details of its findings, and where possible provided colleagues abroad, on a confidential basis, with case notes of the patients investigated. In most cases these notes showed that by non-Soviet standards there were no grounds for compulsory hospitalization.

For these activities commission members have either been forced to emigrate (like Dr Volshanivich) or arrested and charged with disseminating anti-Soviet slander (Article 190/1), or with anti-Soviet propaganda and agitation (Article 70/1). According to Soviet judicial theory, as reiterated recently by Evgenii Smolentsev, Deputy Chairman of the USSR Supreme Court, "in the practice of Soviet courts, there are not and there cannot be convictions for religious and political beliefs" and hence any claim that there are prisoners of conscience in the Soviet Union is anti-Soviet propaganda.

According to TASS, Mr Serebrov pleaded guilty under Article 70/1 and admitted knowing that the documents he helped to prepare would be distributed in the West. TASS further recorded that he had "repented" of these actions, but some Moscow sources deny this "repentance", saying that in such a case a far lighter sentence would be expected.

The British Medical Association has tabled a motion for the September meeting of the World Medical Association in Lisbon, condemning both the use of psychiatric methods for political repression and the suppression of the "Moscow Working Commission".

Vera Rich

UK engineering council

New lambs for old

A new body to safeguard the quality of British engineers is to be set up by Royal Charter, the government announced last week. The Engineering Council, as the body will be known, is the culmination of eighteen months of heated debate since the Committee of Inquiry into the Engineering Profession, chaired by Sir Monty Finniston, recommended that there should be a new organization to oversee the education and registration of engineers.

The Engineering Council's first parttime, unpaid chairman is Sir Kenneth Corfield, chairman of Standard Telephones and Cables Limited. The Department of Industry, which is putting up £1 million to get the council started, will appoint 15-24 board members — for which it has already received 300 suggestions — and a permanent secretariat in the autumn. After a three-year transition period, the council will elect its own members and will be expected to be selffinancing mainly from fees charged for registration, its chief business.

Corfield; engineering's chartered chief

The council is a disappointment to many. Some consider it a poor substitute for the statutory Engineering Authority that Sir Monty's committee had asked for. One issue in the debate has been the relationship between a new body and engineering institutions, especially the Council of Engineering Institutions, which have traditionally chartered engineers and promoted their separate interests through their own Royal Charters. Sir Monty and his supporters fear that the new Royal Charter gives the institutions too much influence. Certainly the new council will not have funds for the improvement of engineering education or even the support of students, as Finniston had asked.

The charter lays down two main roles for the council, each of which it is empowered to delegate in part to the engineering institutions: to determine standards and criteria for the education, training and experience of engineers and to keep a register of those meeting the criteria. Engineers will be eligible to apply for three categories of registration; as professional engineers, technician engineers or engineering technicians. Registration for each category will be in three stages, the first after completing an approved course, the second after training and the third after work experience. Provision is also made for those entering the profession through unorthodox routes. And all those now registered through the Engineers' Registration Board of the Council of Engineering Institutions will automatically be registered with the new council at stage three.

The role of the Engineering Council as registering authority calls into question the future of the Council of Engineering Institutions (CEI). That body, however, expects to carry on with business as usual for perhaps two years until the new council is operating fully. Any change in its status will then mean revoking its own Royal Charter, a move which cannot be taken without a two-thirds majority among its members. The battle for responsibilities could continue much against the wishes of Sir Monty's committee and others who hoped to break the CEI's grip.

Judy Redfearn

University Grants Committee

Biting the bullet

The University Grants Committee considered earlier this year whether it should resign rather than administer the British government's 8.5 per cent cut in support for the universities, according to Dr Edward Parkes, the committee's chairman, in evidence to the House of Commons Select Committee on Education. But, in the end, the committee decided to soldier on, not wishing to be a "fair-weather committee" and believing itself to be the only group with a sufficiently detailed knowledge of the British university system.

Some Members of Parliament were clearly disappointed that the committee had not given them the tangible weapon against the government that a mass resignation would have provided. The select committee was also chagrined that Dr Parkes declined to hand over copies of his correspondence with the Secretary of State for Education, Mr Mark Carlisle, in which — according to his evidence — he had warned the British government of too rapid a contraction of the university system.

Although Dr Parkes's evidence, like that of a delegation from the Committee of Vice-Chancellors and Principals, was taken in private, a transcript of the proceedings was made public last week after the witnesses had confessed themselves puzzled that the hearing had been held in private. Perhaps the select committee had been hoping that its witnesses would have been more open, even gossipy.

Much of Dr Parkes's evidence concerned the criteria his committee had used for allocating funds to the various universities. The relatively favourable treatment for science is apparently accounted for by the "swing back to science" evident in recent applications from would-be students. Within biology, Dr Parkes said that the committee had taken the opportunity to encourage courses and departments with economic potential. Departments of social science. whose student numbers are to be cut collectively by 12 per cent in the next few years, will suffer chiefly at the "soft end" partly on the grounds that student demand is falling and partly because staff-student ratios in some of the departments concerned are too small for good research to be feasible. The grants committee had not, however, been influenced to any substantial extent by "manpower considerations".

Nor, according to Dr Parkes, had regional considerations played a part in his committee's planning except in special circumstances — the argument, for example, that the Universities of Glasgow and Strathclyde should between them be able to provide a full range of courses in higher education to satisfy the needs of students from south-west Scotland, where regional loyalties are strong.

The qualifications of students entering universities had counted in the grants committee's calculations, but Dr Parkes said last week that the committee had tried to strike a balance between institutions with high-quality entering students and those apparently able to provide less highly qualified students with good degrees and useful adult careers.

On the contentious issue of the research records of various departments, Dr Parkes rejected the criticism that too much attention had been given to the success with which departments were able to recruit grant support from the publicly funded research councils. Instead, he argued that industrially supported research usually provided university departments with a measure of overhead support, with the result that the grants committee could legitimately confine itself to the public provision of research support.

The joker in Dr Parkes's pack appears to be the quality of teaching in individual departments and universities, which was also one of his committee's criteria. Insisting that judgements of this kind must necessarily be to some extent subjective, and that little could be done to develop objective criteria based on graduation results, he will not have stilled the charge of prejudice made in the past few weeks by several universities.

Dr Parkes agreed, however, with the vice-chancellors that his committee's ignorance of the other sector of British higher education, represented principally by the 26 polytechnics, is a serious obstacle to sensible planning.

US university research

Industry to provide

Washington

Increased incentives to private companies which support basic research in US universities were contained in a tax package, backed by President Reagan, which was passed by Congress on Monday this week.

The tax incentives were considerably broader than the Administration had initially proposed and unlike that part of the bill dealing with cuts in personal taxation, credits for spending on research received wide bi-partisan support.

Initially the Administration, in its tax package put to Congress in March, had concentrated on shortening the period in which research and development equipment could be written off. Both House and Senate have now passed bills under which such equipment can be fully depreciated over three years, two years less than is allowed for other capital equipment.

The protracted debate over these proposals gave individual congressmen a chance to add their own suggestions for reducing the tax burden on the private sector. One of these is the idea, originally raised by Representative Charles Vanik, that companies should receive substantial credit for money used to support basic research in universities.

When the tax bill was passed to the House Ways and Means Committee, groups such as the Association of American Universities and the American Council on Education argued that such an addition would help offset reduced federal support for university research.

Dr Donald Kennedy, president of Stanford University, told the oversight subcommittee of the House Science and Technology Committee in June that the additional tax credits, which had been put forward in a separate bill sponsored by Congressman James Shannon, would "significantly invigorate" the relationship between industry and universities "without some of the hazards that I see in the present helter-skelter pattern of affiliation".

In the same vein Dr Paul Gray, president of Massachusetts Institute of Technology, told the Ways and Means Committee that tax credits would create an "urgently needed" increase in the flow of corporate funds for university research. At present about \$210 million — or 3.5 per cent — of university research funds is provided by the private sector, the bulk of the rest coming from federal government.

Responding to such arguments, the committee not only included a tax credit for any increased research expenditures, but confirmed that existing tax provisions affecting both gifts direct to academic institutions and to third-party tax-exempt organizations, such as foundations, would persist.

However Dr Kennedy and Dr Gray were

Australasian fellowships

The council of the Royal Society has set up a new research fellowship designed to further the United Kingdom's scientific collaboration with Australia and New Zealand. Main purpose of the fellowship is to improve access to major "facilities" such as unique features of the geological, oceanographic or biological environment, astronomical centres and nuclear physics and biotechnology laboratories.

The scheme is aimed at British and Australasian postdoctoral scientists wishing to undertake research or to learn new techniques. The fellowships last from three to twelve months, and are the result of discussions between the Royal Society, its Australian and New Zealand equivalents, the UK Science and Engineering Research Council and Australasian government departments. The Australasians have yet to find the funds for the scheme, so the Royal Society, encouraged by £15,000 from BP, has forked out £50,000 for the first year of the enterprise. Interested scientists and engineers, or their potential hosts, are invited to apply. Philip Campbell

unable to convince Mr Donald Regan, Secretary of the Treasury, that the extra credits for support of university research should be included in the bill.

The bill was eventually defeated after a bitter fight over the timing of cuts in personal taxes on the floor of the House. But the Republican-sponsored measure which replaced it, with the support of several conservative Democrats, adopted virtually identical language in its section on tax credits for research expenditures within the private sector.

There were some differences. The House bill, for example, includes corporate expenditure for university research in the base from which the additional expenditures, which would be eligible for the tax credit, are calculated. This will substantially reduce the size of the credits over those supported by the committee. In addition, the House bill specifically excludes tax credits for the support of research in the social sciences and the humanities.

The result is that there will be a small credit for basic research as well as a provision that research equipment given to a university, provided it is less than two years old, can be counted by a company as a charitable contribution.

The major question now is whether all the proposals made in the House bill will be agreed by the Senate. At present, however, the Senate version does not include the tax break for basic support in universities. Representatives from the two legislative bodies met this week to iron out their differences; in the absence of significant opposition the university tax credits survived into the final bill.

David Dickson

Brazilian research funding

Sliding backwards

Rio de Janeiro

There is uncertainty and alarm among Brazilian scientists following a series of forums held during the past few months at the request of the Brazilian Association for the Advancement of Science and involving the heads of the various funding agencies. Still no official government policy has been announced, and scientists are very much in the dark about the future of Brazil's science funding.

With inflation at 110 per cent this year and confronted with shrinking research budgets and graduate scholarships, research scientists, particularly those at universities, are concerned by suggestions made by Gerson Ferreira Filho, new director of the Financing Agency for Projects and Studies (FINEP), that his agency would abandon its policy of financing all institutions and only approve funding for specific projects. Support for institutional funding, he said, would be transferred to the Ministry of Education.

The Minister of Education, General Rubem Ludwig, in his turn, has hinted at the possibility of changing the status of 19 federal universities to that of "foundations", capable of "more financial flexibility". This would force the universities to balance their budgets by charging high tuition fees, making Brazil's education system even more discriminatory than it is now. Even with 65 per cent of the Ministry of Education's budget going to higher education, academics point out that the amount is ridiculously small. Education's share of the national budget has fallen from eleven per cent 10 years ago to less than five per cent today. And the Secretary for Higher Education, although admitting at one of the forums that "we've reached the last line of defence at the bottom of the financial pit", has made no proposals for improving the situation in the immediate future.

Another area of concern is the size of the support provided by FINEP, which amounts to \$100 million per year for all fields of science. In principle other funds are available from FINEP for industrial development projects, but these are in the form of loans to private industry and government agencies, rather than academic institutions. Funds are allocated without external review, and this lack of participation of the scientific community was strongly criticized recently in a document signed by fourteen scientific associations.

The problems of inflation have hit particularly hard at those receiving grants and scholarships from the National Centre for Research (CNPq). The recent introduction of fixed ceilings for scholarships was strongly denounced at the forums, and CNPq, with a meagre \$10 million budget, has announced a policy of

increasing the number of scholarships on offer by reducing the size of each one. CNPq's deputy director has agreed to increase the value of grants already awarded to keep them in line with inflation. Fixed ceilings, however, would apply for all new grants and there are rumours that CNPq's own budget will not be adjusted for inflation next year.

When, at one of the forums Senhor Ferreira claimed that this year's budget was 38 per cent higher than in 1980, he was interrupted by one of Brazil's leading economists, Professor Maria da Conceicao Tavares, who demanded "honesty in words", saving that because of inflation a 38 per cent absolute increase implied an effective cut of 60 per cent. Suggestions from administrators that scientists and professional organizations should lobby the government for more funds were quickly rejected by the scientists present, who pointed out that lobbying requires an effective Congress. In Brazil, however, Congress does not even legislate over budgetary matters - as these have been the sole responsibility of the Presidency since 1967.

Maurice Bazin

Soviet plate tectonics

Open approval

Moscow radio has denied Soviet prejudice against the "new global tectonics". On the contrary, according to Moscow radio's world service, there is a "healthy climate" of "perfectly normal scientific controversy" about continental drift and plate tectonics. The radio's science correspondent, Boris Belitskii, said that Western speculations that there are political overtones to the controversy are "quite absurd".

As evidence, Belitskii cited two tributes which appeared in Soviet learned journals last year on the centenary of the birth of Alfred Wegener. One article, said Belitskii, was written by a strong opponent of Wegener's views, Dr Evgenii Milanovskii, while the other was written by an enthusiastic supporter, Dr Portnov, thereby making nonsense of Western "mischiefmaking insinuations".

Nevertheless, Belitskii acknowledged that many Soviet geologists do not support plate tectonics, considering that the theory cannot account for many aspects of continental structure and evolution.

Whether this leads to bias, or a stifling of opinion, is not clear. Some who know the Soviet Union say that discussion among geologists is now quite free. At the same time, geophysical articles in the general and semi-popular media tended, until recently, not to support plate tectonics. One of the first approving popular articles was a progress report on the Baikal-Amur Mainline railway which observed in passing that, owing to continental drift, the line, when completed, would be some 50-70 cm longer than originally planned. Vera Rich

Chinese university development

Help from afar

Washington

The World Bank and its soft-loan subsidiary, the International Development Association, have agreed to lend \$200 million to the People's Republic of China to support the country's efforts in meeting its present shortage of trained scientists and engineers. The loan is the first to have been made to the republic since the country assumed China's representation at the World Bank from Taiwan last May and is the biggest loan ever made specifically for building up a nation's scientific and technological base.

Half of the money will be provided by the World Bank at its standard interest rate of 9.6 per cent a year over 20 years, and the other half comes interest-free over 50 years from the International Development Association. The loans will go directly to supporting China's University Development Project, which includes among its aims an increase in the enrolment of science and engineering students at 26 leading universities from 92,000 to 125,000.

In addition, the money will be used to introduce graduate degree programme, to improve the general quality of teaching and research, and to strengthen the management of universities and the Ministry of Education.

According to World Bank officials, the government of the People's Republic of China will contribute an extra \$95 million to the University Development Project as part of a general effort to increase undergraduate enrolment by 7 per cent a year up to 2.2 million in 1990. Graduate programmes will raise their enrolments from virtually zero to 200,000 by 1990.

Of the total amount of \$295 million for which the project has at present budgeted, about \$160 million will be used to buy instructional and research equipment. Most of this will be obtained through international competitive bidding, a standard requirement of World Bank loans. Preference will be given to local manufacturers, but World Bank officials admit that "the amount of equipment contracts to be awarded to local suppliers through international competitive bidding is expected to be small".

China's determination to proceed with its plans for science and technology education contrast with its decision substantially to reduce previous commitments to the purchase of capital research equipment. Plans for obtaining both a particle accelerator — which was to have been built to designs produced by the US Department of Energy — and a telecommunications satellite which was to have been provided through the National Aeronautics and Space Administration, have both been shelved because of the lack of available capital.

David Dickson

CORRESPONDENCE

Creation "copout"

SIR — In a critique of American Creationism (Nature 2 July, p.95), Darnbrough, Goddard and Stevely state "no plausible theoretical model exists which provides a mechanism for the spontaneous generation of nucleic acids as informational macromolecules specifying polypeptides which themselves mediate the replication and expression of that information". This statement is much like the definition of the same scientific chicken-egg problem by J. Monod (1971) and K. Popper (1974).

One can argue plausibility indefinitely because the assessment of that quality is highly subjective. However, there has appeared. through experimental demonstration, a laboratory model of a cell-like structure with many of the properties required. This structure is composed of lysine-rich and acidic thermal polyamino acids that complex with each other to form cell-like structures. Both in solution and in suspensions of particles, these (selfordered) polyamino acids catalyse simultaneously the formation of pentides and polynucleotides from ATP and free amino acids (see ref.2). This model so far leaves unanswered many of the questions about the origin of the genetic code, but it demonstrates that the question is not as scientifically imponderable as Popper and Darnbrough et al. have suggested. It does provide answers to some questions, such as how the two kinds of macromolecular synthesis could first have been closely coordinated. The sequence theoretically derived from those experiments is: amino acid sets → protocells → nucleic acid + protein

I would not criticize Darnbrough et al. for not being aware of advances as recent as these (further details in the press). However, to attack an area of science because it has not yet reached a given stage, and then to argue a need for resorting to supernatural explanations because specific scientific answers are not reported, consolidated or agreed upon, is what is referred to in an American idiom as a "copout".

SIDNEY W. FOX

University of Miami, Coral Gables, Florida, USA

Attack on Tamuz

Sir — The editorial entitled "Making Israel Atone for Tamuz" (Nature 18 June, p.523) has shocked and dismayed many of your faithful readers. It appears that Nature, a journal that has hitherto enjoyed an unparalleled reputation in the scientific community for publishing innovative and careful scientific observations, is now embarking on a new course as a "yellow sheet" of political comment. One can only fear that subjective, biased, political diatribe as represented by your editorial will sully and finally displace the elegant work that has heretofore been the mark of publications in Nature.

I must admit that the editorial was cleverly written. Under the guise of a great concern for the reputation of the Non-Proliferation Treaty the editorial proceeds to mount a political attack on Israel and depicts Iraq, a signatory of the treaty, as an innocent, wholesome and wronged party, even deserving financial redress through "international legal processes" for the destruction of its means for producing awesome weapons.

Scientists are wont to deal with observations and to derive probability statements for predicting future phenomena based on past observations. Let us apply some logic to the editorial at hand. Unfortunately, although Iraq is a signatory of the Non-Proliferation Treaty, past actions have shown that in the case of Iraq "the sword is mightier than the pen". In the course of history the signatures of dictatorial governments have proved worthless. Iraq, by its own declaration, has maintained a continued state of war with Israel and has recently branched out in its military adventurism by an unprovoked attack against its neighbour, Iran. Iraq has been at the forefront of frenzied calls for the total destruction of Israel and has given both financial and military support to the terrorists who have revelled in the wanton murder of innocent civilians, especially women and children. Parenthetically, I did not note editorials in Nature either denouncing the bombing attack by Iran, albeit unsuccessful, against the nuclear reactor in Iraq, or decrying the slaughter of innocent women and children in Israel by terrorist attackers.

The editorial does not at all address the question as to why Iraq was stockpiling uranium suitable for the manufacture of atomic weapons. Much faith is placed in international commissions and the cursory inspections of the Iraqi reactor. It is ludicrous to believe that a government bent on production of nuclear weapons could not hide such facilities. Furthermore, what good is the knowledge that nuclear weapons are being produced once all the production capabilities, including the raw materials, are in place? Would a contrite editorial in Nature bring back to life the many thousands of casualties that would result from even one atom bomb dropped on Israel? Or might the response to such an unthinkable event be equivalent to the world response witnessed during the Nazi outrages? Even the United States government was quite concerned by Iraqi intentions as evidenced by the testimony of Mr Roger Richter before the US Senate Foreign Relations Committee.

As a native-born American, and a former officer in one of the US uniformed services, I am offended by the ugly term "Zionist vote". Fortunately, the majority of American voters speak to reality, and feel an affinity for Israel as the bastion of an open and democratic society in an area where tyrants and dictators prevail.

Unfortunately, the threat of nuclear retaliation is perhaps the only deterrent that Israel has against total annihilation by its truculent neighbours. Indeed, it appears that not only does Israel require this deterrent against its threatening neighbours, but perhaps also against such editorials as that in *Nature*.

Finally, aside from the question as to

whether one does or does not justify the Israeli destruction of the Iraqi nuclear reactor, I believe that one can assert that editorials of political diatribe do not belong in a premier scientific journal such as *Nature*.

S.Z. HIRSCHMAN

Mount Sinai School of Medicine of the City University of New York, New York, USA

Certain points raised in this letter have been discussed in a subsequent editorial (Nature 16 July, p. 185) — Editor, Nature.

Researchers insecure

Sir - "Poaching" of ideas and staff between competing institutions is not a new phenomenon (A.J.S. Davies, Nature 2 July, p.96), though I doubt if it has (yet) reached serious proportions. A more serious problem, exacerbated in recent years by economic constraints, is that research teams usually include several young postgraduate and postdoctoral workers financed by short-term grants of 1-3 years' duration. The present system by which these are made available does not permit, let alone encourage, such scientists to remain in the teams where they begin to develop their expertise. There are two powerful reasons in particular for this. One is the present dire shortage of permanent posts in the academic sphere. The second is that it now appears to be the general policy that a young scientist should not be the recipient of more than 2 three-year grants from such bodies as the Medical Research Council. Consequently, after 6 years, such people may be obliged to find other employment anyway.

In most cases, the prime motivating force for a young scientist is not so much the chance to earn a large salary as reasonable security in order to develop his or her own skills and ideas over the long term. To be in a constant state of anxiety for the future, no matter what one achieves, seriously undermines one's ability to do this. Sadly, neither the universities nor the major funding bodies (the government and research councils) in Britain seem to have grasped this simple concept.

A certain degree of flexibility for movement between institutions is highly desirable, but many young scientists would welcome a contract that bound not only them but also their employer in the long term. Present conditions in Britain promote academic paralysis by destroying flexibility — those with secure jobs stick to them — while denying encouragement and opportunity to the young, and with that the long-term success and wellbeing of research teams.

MICHAEL W. RUSSELL

University of Alabama, Birmingham, Alabama, USA

Erratum

In a letter published in *Nature* 14 May, p. 104, the name of one of the members of the (US) Xeroderma Pigmentosum National Registry was omitted. The full list of members is: Alan D. Andrews, James L. German III, Kenneth H. Kraemer and W. Clark Lambert.

NEWS AND VIEWS

Towards a total human protein map

from Brian F.C. Clark

Now that such powerful techniques are available for the sequencing of DNA and the study of genome organization, some scientists are turning to what might be the next large-scale challenge — the separation, identification and measurement of the gene products.

At a recent workshop*, the possibility of making a complete catalogue of animal cell proteins using two-dimensional gel electrophoresis was discussed. In man there are at least 30,000 different proteins (although maybe only 10,000 in a given cell type) and the technique has already been used to separate and catalogue more than 1,200 of them (R. Bravo et al. Cell Biol. int. Rep. 5;93, 1981).

At the workshop it was confidently stated that it will be possible to detect 2,000 to 3,000 proteins with present technology. Further progress can be made by fractionating cellular components before carrying out two-dimensional separation. This will bring many proteins present in small amounts to the level at which they can be detected.

There are three main problems in trying to produce a catalogue of proteins for human or any other animal cells: how to make methods of protein identification reliable and reproducible; how to store the immense amount of data produced in a usable form; and how to name and catalogue the separated proteins.

The question of reproducibility is clearly the most serious problem and needs to be solved first. At present gel chemistry is not under complete control and, among the many parameters discussed, it was generally agreed that the first essential is the standardization of the commercial production of ampholytes for the first separation by isoelectric focusing. Attempts have been made to overcome standardization problems by R. Bravo (University of Aarhus), L. Anderson (Argonne National Laboratory) and J. Garrels (Cold Spring Harbor Laboratory) and a representative of a commercial concern expressed confidence that the requirements of the research scientists could be met in the future. Indeed, an

arrangement was to be made to provide specified laboratories with samples of ampholytes until all appropriate criteria were met. Since future automatic measurements and clinical applications depend on the reproducibility of the technique, this arrangement was of great significance for the workshop.

In the two-dimensional separations it is now usual to take a total cellular protein extract which can be radioactively labelled, denature it, and apply it to two different first dimensions. Isoelectric focusing is used to separate neutral and acidic proteins and non-equilibrium pH gradient electrophoresis for the basic proteins. After the first two dimensions have been run, each separated sample is applied to an identical polyacrylamide gel containing SDS to provide the second dimension of electrophoretic separation.

J. Garrels' laboratory routinely standardizes total protein extracts by using a number of different concentrations of polyacrylamide and several pH ranges. In a simpler, two-dimensional standardization (in cases for which it is justifiable to lose some basic protein resolution) his group runs only a broad-range (pH 3.5 – 10) isoelectric focusing electrophoresis for the first dimension

After separation the protein locations on the gel have to be visualized. Discussion was rather brief but there was a general consensus that fluorography provided a better and more accurate method than autoradiography. With unlabelled proteins the recently used silver stains are much more sensitive than Coomassie blue but produce variable results with gels more than one millimetre thick.

The problems of data handling are obviously immense - even at the present time more than 1,300 proteins may be recorded in different cell types and under different conditions, and L. Anderson reported that his laboratory has already run 40,000 separations. There was, however, much optimism about current progress. Already it seems that automatic measurements of protein locations, together with computer storage and retrieval, will be possible in the laboratories of N. and L. Anderson, J. Garrels, K. Lonberg-Holm (Dupont), L.E. Lipkin and P.F. Lemkin (NIH) and E.P. Geiduschek (University of California, San Diego)

within the next year. Since these laboratories have access to medium-sized computer facilities, it was reassuring to small laboratories that A. Freiburghaus (University of Cambridge) was also optimistic of finishing his plans for general automatic measurement of two-dimensional gels using more standard university facilities.

There was general agreement on the best approach to the third problem, that of the naming and cataloguing of the proteins. It was felt that, at present, any system relying on accurate positional information was doomed to failure and that it is far too early to try to set up a master nomenclature. Estimates of when this might be possible varied from three to five years. With this problem in mind, the Aarhus group described the advantages of labelling small numbers of cells with ¹⁴C -labelled amino acids so that raw data may also be preserved for long periods.

Different nomenclatures will probably be necessary for different cell types. It was agreed that the current different nomenclature systems used in different laboratories should continue but with the intention of switching to a master plan when the separations can be suitably reproduced. Meanwhile, it was agreed that laboratories involved in cataloguing cell proteins should exchange samples and marker proteins so as to be able to crossrefer to separations in different laboratories. If the cross-referencing were done, then it should be possible at future workshops to assemble the available information (tissue specificity, modifications, hormonal responses) for the 100 or so most prominent proteins and to publish a compendium of such data with representative maps. The problem of protein identity was also discussed and a general appeal was made to anyone working with purified identified proteins to allow them to be located on the standardized two-dimensional gel separations.

The workshop forecast that within a short time several data sets of catalogued proteins will be established in the USA and Europe. Possible locations would be the Argonne National Laboratory, Cold

Brian F.C. Clark is Professor in the Division of Biostructural Chemistry, Department of Chemistry, Aarhus University.

[•] The EMBO workshop on 'The standardization of a numbering system of animal cell proteins separated by twodimensional gel electrophoresis' was held at Aarhus University, Institute of Chemistry, June 30 and July 1 1981, and was organized by J.E. Celis of the Department of Structural Biochemistry, Aarhus University.

Spring Harbor Laboratory and the European Molecular Biology Laboratory.

It was agreed that it was desirable to support a number of future research projects to obtain as complete a catalogue of proteins as possible for a small number of centrally important cell types. Probably the laboratories of L. Anderson, J. Garrels and J.E. Celis would concentrate at first on HeLa, human fibroblast, human lymphocyte and mouse fibroblast cell types. The choice of the last cell type arose from the availability of genetic data for the mouse which, in future, will allow changes in the protein map to be related to changes in genotype. In this respect J. Klose (University of Berlin) described promising results from experiments in which he identified a small number of protein changes in mouse cells treated with the mutagen methylnitrosourea.

The great potential of the method in clinical diagnosis was described by E. Jellum (University of Oslo) and L. Anderson. Jellum described the 'Janus collection', an impressive stock of human blood samples from 63,000 patients set up in Oslo in 1973. Since the patients have had samples taken yearly, when they develop a

new disease it is possible to search through their protein record for several years before the disease was detected. Clearly a catalogue of human gene products could make it possible to detect metabolic irregularities and diseases, such as cancer, which affect gene expression.

In terms of current costs, J.E. Celis's group has estimated that one two-dimensional gel analysis can be made for thirty dollars, using ¹⁴C-amino acid labelling of cells. For the development of a computerized program for handling large numbers of reproducible analyses and the establishment of a human protein catalogue, the Argonne National Laboratory has estimated that a sum of the order of ten million dollars is required. The general impression given by the research workers involved was that a grant of a million dollars a year would be feasible from US granting agencies.

The meeting ended on an optimistic note with the belief that present technical problems can be solved, and plans for cooperation and for communication of unpublished data among the laboratories which are developing the technique can be implemented.

hormone.

Mouse mammary tumour virus (MMTV) is a RNA virus that may be transmitted as a virion, producing mammary carcinomas in female mice and productive infection in rodent tissue culture cells. Like other RNA tumour viruses, it replicates by synthesizing a viral DNA copy. MMTVlike DNA is also present as an endogenous provirus in the genome of mice. In mammary tumour cells and in virusinfected cells, glucocorticoid hormones rapidly and dramatically enhance the rate of synthesis of MMTV RNA. Two recent papers from the Swiss Institute for Experimental Cancer Research describe the cloning of MMTV DNA, the introduction of that DNA into mouse tissue culture cells and the regulation of MMTV RNA expression in the cells thus transformed. In one case, the full genome of MMTV was cloned from the closed circular DNA of infected rat hepatoma cells (Buetti and Diggelman Cell 23: 335. 1981). In a second approach, the MMTV provirus and flanking host cell sequences were cloned from a mouse liver DNA library (Hynes, Kennedy, Rahmsdorf and Groner Proc. natn. Acad. Sci. U.S.A. 78: 2038, 1981). In each case the cloned DNA was introduced into thymidine kinasedeficient mouse L-cell fibroblasts, cells that have glucocorticoid receptors. The now-standard technique of co-transfection with DNA containing the herpes thymidine kinase-proficient cells was used to introduce the MMTV DNA. In this way, L-cell clones, each carrying multiple copies of the MMTV DNA, were obtained. Treatment of the transformed cells with the glucocorticoid dexamethasone resulted in a 5-10-fold increase in the level of poly-(A)-containing MMTV RNA. Expression of the cloned DNA was thus shown to respond to hormone in a manner similar to that found in cultured mouse mammary tumour cells or virus-infected rodent cells.

Hormonal regulation of another cloned gene is reported by Kurtz of the Cold Spring Harbor Laboratory (Nature 291; 629, 1981). The rat protein α_{2U} globulin is synthesized in liver and excreted in urine. It is regulated in vivo by multiple hormones. including glucocorticoids, which enhance, and oestrogens, which suppress, its synthesis. The protein is encoded by a multi-gene family. Two of these genes were cloned and the cloned DNA introduced into L cells using the herpes thymidine kinase co-transfection technique. L-cell clones transformed with one of these genes showed dexamethasone-induced enhancement of α_{211} globulin mRNA levels in 8 of 12 cases, and transformation with the other gene conferred a positive response in 4 of 9 clones. Again, individual L-cell clones each carried multiple a_{211} globulin gene copies.

The question of how glucocorticoids regulate genes is but a fragment of the problem of differential gene expression, of how genes are turned off and on by differ-

Hormonal regulation of cloned genes

from Philip Coffino

How do steroid hormones work? Glucocorticoids and the sex-related steroids, oestrogens, progesterones and testosterones, have profound effects on development and differentiation. A consensus exists on the early and late steps of their action. The hormones enter a cell and bind to a specific cytoplasmic receptor. The steroid-receptor complex undergoes a structural change that results in its entry into the nucleus. In the nucleus a series of events ensue that lead to an increased rate of transcription from specific genes, with a consequent increase in the steady-state level of mRNAs generated from these transcripts. (Other mechanisms, such as changes in mRNA stability, may also play a part in some cases.) The nature of the events involved in transcriptional regulation by the steroid-receptor complex in the nucleus is obscure.

This problem is a special case of a more general one: how is gene expression controlled to produce cellular differentiation

Philip Coffino is in the Departments of Medicine and of Microbiology and Immunology, University of California, San Francisco, and is currently on sabbatical at the Institut de Chimie Biologique, Strasbourg.

and modulated by hormones and other physiological effectors in differentiated cells? Cloning of eukaryotic genes in recent years has yielded considerable information on gene structure, but relatively little on regulation. Cloned genes, for example globin and ovalbumin, have been placed in cells and shown to function there. However, in their new environment, these genes did not respond to the regulatory signals that work in vivo. Recently, a series of papers has demonstrated that hormonedependent control of expression can take place in cloned genes put back into cells. This work and natural extensions of it promise to help elucidate the molecular mechanisms of steroid hormone action.

An attractive model, derived from our understanding of how gene expression is managed in bacteria, postulates that the steroid hormone-receptor complex binds with specificity and high affinity to a region of DNA which lies near the gene whose transcription it regulates. The model predicts, as has now been found possible in two distinct systems, that isolated DNA containing the regulable gene, introduced into a hormone-responsive cell, should show regulation dependent on the

entiation and by physiological changes. The studies described here show that, placed together, a cell and a cloned gene can modulate the level of that gene's RNA product in response to a glucocorticoid. The nature of the contribution of each is not resolved. Does the hormone-receptor complex interact directly with sequences in or near the cloned gene, in flanking host cell sequences or at more distant sites? Do all copies of the gene function, or only some, and if the latter, what distinguishes the responsive copies? Is the regulation shown here transcriptional or does it lie at the level of RNA stability or processing? Why do the cloned genes work at all in L cells? In the case of MMTV the gene is already there in the form of a provirus, but is not expressed, while the normal functional environment of the α_{211} globulin gene is a liver cell, not a fibroblast. Can these differences in function be accounted for in terms of chromatin structure, DNA methylation, the nature of flanking sequences or in some other way?

It is probable that we will soon have answers to those and related questions. The MMTV α_{211} and other hormone-responsive genes, natural or constructed, will be sequenced, cut, modified and asked to perform in cells, and the transformed cells' DNA and chromatin will be picked at with nucleases and restriction enzymes. Experiments of this kind will define the elements needed to make the system work and this understanding will guide efforts to design a fully defined hormone-regulated in vitro transcription system constituted of purified components. A crucial early step of this ambitious programme has been achieved and the rest will find no lack of willing hands.

Eruption mechanics on the Earth, Moon and Mars

from G. Wadge

THE discovery of volcanic eruptions on Io by the Voyager 1 spacecraft1 was exciting visual proof that volcanism, in this case based on sulphur, is a major process on the surface of at least one planetary body other than Earth. There is abundant, though less spectacular, visual evidence of past volcanism on Mars and the Moon; most of this volcanicity occurred in the early history of these planets. Volcanologists are faced with the problem of how to interpret this evidence in terms of eruptions which ended billions of years ago. One of the most productive methods has been to compare the known magma properties and conduit systems of volcanoes on Earth with the equivalent putative values for the other planet, deduce what volcanic landforms these eruption mechanics should produce and see whether these agree with the observations. Recently Wilson and Head2 reviewed the mechanics of erupting basaltic magma on the Moon using this approach. Their conclusions, perhaps rather surprisingly, generally emphasize the similarities between terrestrial and lunar flood basalt eruptions.

On both bodies magma rises to less than 2 km below the surface before gases begin to exsolve, mainly H₂O and CO₂ on Earth, and CO on the Moon. Wilson and Head assume that CO is the main lunar volatile phase and is soluble in silicate magmas —

but there is little direct evidence. The rates of rise of magma before this vesiculation are limited by the degree of cooling and the attendant increase in viscosity, and by the yield strength of the magma. Wilson and Head find that a very small range of conduit widths (0.1-4 m) is adequate to explain the whole spectrum of terrestrial eruptions, from the magma that barely reaches the surface to gigantic eruptions exemplified by the Columbia River flood basalts. The most striking feature of lunar volcanism is the great length and volume of many of the recognizable mare flows. This study clearly shows that the feeding fissures of these huge, high-effusion rate eruptions need to have been only slightly wider than those on Earth, perhaps 10-25 m. We see little evidence of these source fissures on the Moon and should not expect to, for they are too narrow.

Lunar basaltic magmas came from deeper sources (~100 km) than most terrestrial basalts and were also relatively denser compared with the overlying crust. Buoyancy is presumed to be the main force responsible for magma rise on the Moon as it is on the Earth. Thus lunar magma pressures should have been lower and the effusion rates less than terrestrial values. This conclusion is contrary to the observed size of the lava flows. A hydrostatic solution to this problem was proposed by Solomon³ involving regional loading outside the mare basins. Wilson and Head now show that magma density contrasts were of the same order as those calculated for Earth (a few hundred kg per m³). The large magnitude of the lunar eruptions was due to the local extensional tectonic environment around the mare which allowed particularly wide fissures to develop. Lunar effusion rates were probably not exceptionally large compared with those for terrestrial flood basalts. What is remarkable is that some of the calculated eruption volumes (10³-10⁴ km³) represent a significant fraction of the total volume of mare volcanism (~10² km³).

CO concentrations in lunar basalts were probably about an order of magnitude less (a few hundred p.p.m.) than average volatile contents of terrestrial basalts. As magma rose to the surface, this relative deficiency of volatiles would be compensated by an increased release of energy per unit mass due to the decompression to zero atmospheric pressure at the surface. The resultant disruption of magma into fragments would allow wide dispersion but the lack of an atmosphere would preclude the complex differential sorting processes typical of terrestrial pyroclastic eruptions. Instead, spectacular fountains of magma clots must have blanketed large areas around lunar vents, and in many cases these clots, uncooled by atmospheric interaction, would have recoalesced on hitting the ground to form lava flows.

Unlike the Moon, Mars has a thin but appreciable atmosphere and a gravity field intermediate between those of the Moon and Earth. One would expect martian volcanism to be a hybrid of the characteristics displayed by its planetary neighbours. Preliminary calculations, again by Wilson and Head4, indicate that it should resemble Earth volcanism more than that of the Moon. They predict vigorous, convecting eruption columns, growth of gas bubbles in magma to about four times the equivalent size on Earth, and the common occurrence of high-pressure, explosive vulcanic eruptions caused by magma interaction with sub-surface ice. Of course, we know less about the tectonic setting and much less about magma compositions on Mars than we do for the Moon. If these factors are not too different from the values assumed by Wilson and Head, then martian eruption mechanics should make the development of ignimbrites, by the collapse of large emption columns, even more common than on Earth. Can we see these ignimbrites? The answer given by Greeley and Spudis in their review⁵ of the Mariner and Viking data is that despite several claims for their identification, unequivocal proof is lacking. Failure to identify ignimbrites on Mars could necessitate revision of the eruption models of Wilson and Head although it is more

probable that we need to look longer and more closely.

The calculations of Wilson and Head assume that the pressure gradients driving erupting magma are equal to the lithostatic gradients — a reasonable assumption for generalized modelling. It is clear that this does not hold for all eruptions on Earth. Repeated fracturing and deformation of

the surface during the eruption of central volcanoes is proof of this. Mars has huge central volcanoes which, like their terrestrial counterparts, exhibit a variety of evolutionary forms and undoubtedly have complex internal structures. In future we will need to incorporate elements of these massive surface structures into models of martian eruption mechanics.

Sedimentary sulphides

from Philip Trudinger and Preston Cloud

THE recognition that present reserves of minerals may be nearing exhaustion has increased interest in the help that models of ore genesis might give in the search for deep-seated deposits of commercial-grade minerals. That some strata-bound base metal sulphide ores may have formed syngenetically, that is, in the early stages of sedimentation, by deposition in sedimentary pile rather than by hydrothermal replacement was first proposed in the early 1950s. Since then, syngenetic models have been proposed for many deposits and often imply lowtemperature deposition with the involvement of biological activity in mineralization. A timely review of evidence for and against biological and other syngenetic processes in sulphide ore genesis was provided at a symposium* held in Australia earlier this year.

The characteristics of strata-bound sulphide ores were described by L. Gustafson (Australian National University, Canberra). The strata-bound sulphide and sediment-hosted lead-zinc and copper ores are features of the oxygenous Earth, and are no older than 2 Gyr. The deposits are in tectonically active intracratonic settings, commonly associated with volcanism, with indications of aridity or hypersalinity. The local settings are ones in which groundwater can move to shallow sites of sulphide deposition. The deposits are characteristically associated with redbeds, either beneath or interbedded with them. This is particularly true of copper ores, most of which are found in reduced sediments, often at a redox interface; for example, between red and green sediments. Zoning patterns are usually related to 'plumbing systems', both stratigraphically and areally. The timing of metal fixation

relative to deposition and diagenesis, and the temperature of mineralization, are of crucial importance but are, as yet, poorly understood. Sulphur isotope values reflect processes at the sites of deposition rather than the source of the sulphur. Finally, unlike volcanogenic deposits which range across the copper-zinc axis on a lead-zinc-copper ternary diagram, the strata-bound copper and lead-zinc deposits mostly cluster in the copper corner or line up along the lead-zinc edge respectively.

Gustafson emphasized the problems arising from variable usage of the terms syngenesis, diagenesis (processes taking place after sedimentation) and epigenesis (processes taking place after sediments are compacted). Different scientists draw their boundaries at different places. He concluded that most of the deposits in question are diagenetic, with metals derived from within the sedimentary sequence but outside the areas of ore deposition. Local reduction of sulphate is probably responsible for deposition of most copper and some lead-zinc, but more than one source of sulphur and mechanism of fixation exists. Variations are, however, observed towards both later epigenetic, and earlier syngenetic, processes.

Several papers dealt with specific ancient strata-bound sulphides - especially the Mount Isa ores of north-west Queensland. the McArthur deposits of Northern Australia, and the Mt Gunson copper deposits of the Stuart Shelf, South Australia. Methods of investigation included isotope tracers, mass-transfer modelling, fluid inclusion palaeothermometry and palaeosalinity, detailed stratigraphy and petrology and biogeochemistry. A consensus of opinion favoured a penecontemporaneous origin for the lead-zinc-silver ores at Mount Isa and McArthur, compared with an epigenetic hydrothermal origin for the associated copper ores at Mount Isa. The ore metals and most of the sulphide were introduced by exhalative processes although there is evidence that some of the sulphide in pyrite was of biogenic origin. Local karst-associated mineralization also occurs in the McArthur region, which further displays redox-related mineralization in the Woologorang Formation, some 3,000 m below the well known HYC deposit.

Further evidence against 'biogenic' lead-zinc mineralization is the presence of saddle dolomite in carbonate host rocks of many lead-zinc occurrences. The mineral indicates relatively high temperatures (up to 150°C) and is perhaps formed along with sulphides during inorganic sulphate reduction.

At Mt Gunson, copper-iron sulphide minerals hosted by laminated mudstones and dolostones are of two generations. The sulphur itself was introduced at the same time as ancient coastal sediments and then reacted with sedimentary iron to form pyrite. This was replaced by copper introduced along faults and other channelways.

C.C. von der Borch (Flinders University, South Australia) outlined how studies on modern depositional systems can lead to a better understanding of sedimentary controls on ore deposition. Noteworthy are deposits in oceanic rift zones (for example, the Red Sea and East Pacific Rise), which provide information on the sources of metal-enriched hydrothermal fluids, and contemporaneous deposition of metal sulphides, in settings analogous to some major ancient deposits. By contrast, modern shallow marine, subaerial and lacustrine sediments, while often resembling ancient counterparts that host stratiform and strata-bound ores, rarely contain metal sulphide concentrations significantly above background.

The main factor controlling metal sulphide accumulation in reducing sediments remote from hydrothermal influences appears to be the supply of reactable metals rather than of sulphide. In many present-day shallow marine sediments, and in some deep-sea sediments, bacterial sulphate reduction is of sufficient intensity to generate sulphide concentrations one to two orders of magnitude higher than those actually observed. In the Holocene paralic carbonate complexes in northeastern Spencer Gulf, South Australia, low levels of metals limit mineralization even though the hydrological regime of this environment resembles those inherent in a number of models of ore genesis.

Potential environments for large-scale biogenic sulphide deposition are those in which metal-enriched groundwaters mix with organic-rich, sulphidic sediments—perhaps exemplified by the Denali chalcopyrite—pyrite deposit in Alaska. The possibility of deposits containing sulphide of both hydrothermal and biogenic origin

^{*}A symposium on Sulphide Mineralization in Sediments: Current Status of Syngenetic Theory was held at the Australian Academy of Science, Canberra, from March 2 to 4, 1981. It was sponsored by the Baas Becking Geobiological Laboratory and formed part of the programme of IGCP Project 157 on Early Organic Evolution and Mineral and Energy Resources. It was attended by over 100 scientists from the mining and petroleum industries, universities and government research laboratories. Abstracts and several full papers will be published in December 1981 in the Bureau of Mineral Resources Journal of Australian Geology and Geophysics 6, No. 4.

Philip Trudinger is in the Baas Becking Geobiological Laboratory, Canberra, and Preston Cloud is Emeritus Professor at the University of California, Santa Barbara.

is suggested by isotopic studies on the McArthur deposit and on the modern sediments of the rift-related Guaymas Basin, Gulf of California.

Although it is now well established that bacterial sulphate reduction is a significant and rapid biochemical process in modern anoxic sediments, caution was advised in extrapolating local rates of sulphate reduction to regional models of mineralization. Rates are affected by many factors, including abundance of organic matter, rate of flow of interstitial water, bioturbation and, for intertidal sediments, the amount of time the sediment is wetted.

Sulphur isotope data are frequently used in inferring the origins of mineral deposits and in interpreting the diagenesis of sulphur. The interpretation of such data is not, however, without difficulties. Patterns of δ^{34} S frequencies in sulphides of modern sediments can be related to the supply of sulphate (open versus closed systems) but not to geological settings. In the reducing sediments of the Bali Trough, 32S in pyrite increased with depth, a trend similar to those reported for cores from the McArthur and Kupferscheifer deposits but which at present defies explanation. However, broad trends in the isotopic compositions of ancient minerals with time are perhaps more amenable to interpretation and suggest that sulphate became the major sulphur component in the hydrosphere, and bacterial sulphate reducers widespread, at about 2 Gyr BP. Anomalous δ^{34} S distributions in 2.7-2.8 Gyr old sulphides of the Michipicoten and Woman River deposits could have resulted from reduction of an oxidized species (sulphite?) other than sulphate.

Further papers dealt with the production and diagenesis of organic matter, the driving force for all biogeochemical processes, and the significance of organic carbon in ancient deposits. Benthic oxygen-evolving prokaryotes were seen as major organic carbon producers in marginal aquatic environments of arid and semiarid climates. Both field and laboratory studies indicated, however, that the bulk of the organic matter is rapidly remineralized, particularly by sulphate-reducing bacteria.

In relatively young sediments, specific organic molecules of diagenetic origin provide clues to sources of organic matter (for example, marine versus non-marine), depositional environment (oxic compared with anoxic) and maturity of organic matter. With time, carbonaceous material undergoes a complex series of reactions leading to loss of volatiles and formation of different products - kerogen, fossil fuels or graphite. Even graphite may be oxidized to CO₂ by water at above 200°C, and can be removed from the system without trace. Thus, while reduced carbon (or graphite) occurs in sediments of all ages, including the 3.8 Gyr old metasediments at Isua, south-west Greenland, its significance can prove difficult to determine. Nevertheless,

considerable progress has been made towards identifying major biogeochemical evolutionary events in Proterozoic and older history through the use of carbon isotopic data on kerogens, together with fossil and other geochemical evidence. These data are now all consistent with the view that oxygenic photosynthesis had evolved by the late Archaean and that, thereafter, first the hydrosphere and then the atmosphere were progressively oxygenated.

The symposium highlighted advances made over the past decade in our knowledge of mineral deposits and modern

depositional systems. It stressed the need for continuing multidisciplinary research on the evolutionary cycles of elements involved in the making of either sedimentary ore deposits or fossil fuels. These cycles are, or may be, affected by biological processes at some stage in their history. Whether that is called syngenetic or diagenetic seems to be more a matter of discipline and definition than of timing. To the extent that we detected consensus, it was to the effect that major sulphide deposits seem to include both post-depositional sedimentary and later hydrothermal components.

Synthesis and function of metallothioneins

from J. Kägi, T.L. Coombs, J. Overnell and M. Webb

As cadmium is a ubiquitous component of the Earth's minerals, its transfer to animals and man through food chains cannot be avoided. Since the metallic ion is cumulative, long-lived mammalian species, even in uncontaminated environments, can accumulate appreciable body burdens of Cd2+ during their lifetimes. Most of this Cd2+ is stored in the liver and kidneys as a soluble lowmolecular-weight metalloprotein which contains not only appreciable amounts of Cd2+ and Zn2+, but also an extremely high number of cysteine residues. The metalloprotein, named 'metallothionein', is a metallo-derivative of the sulphur-rich apoprotein, thionein. Thionein is an inducible protein and synthesis of usually short-lived metallothioneins, in which Zn2+ and Cu+ are the major bound cations, occurs when the intakes or body burdens of these 'essential metals' are

An explosive increase in interest in these metalloproteins followed observations in the 1960s that they accumulate in the liver and kidneys of rabbits in response to administration of cadmium salts. As there was evidence from Japan of a relationship between cadmium pollution and the Itai Itai disease, the hypothesis was put forward that the inducible synthesis of metallothionein formed a defence mechanism. Evidence soon accumulated that besides participating in cadmium sequestration, metallothioneins play a fundamental part in the homeostasis of certain essential cations, principally Zn2+ and Cu2+, a function undoubtedly dependent upon their primary, secondary and tertiary structures. Analysis of recent developments in the chemistry of metallothioneins, with its implications in biochemistry, nutrition, toxicology and medicine, formed the main objective of a recent meeting*.

Sequencing and physico-chemical

Sequencing and physico-chemical studies (J.H.R. Kägi, University of Zurich) show how the primary and tertiary structures have been conserved during many evolutionary stages. From UV, circular dichroism and magnetic circular dichroism spectroscopic studies on experimentally prepared cobalt(II)- and nickel(II)-metallothioneins, as well as the natural zinc- and cadmium-proteins, M. Vasak (University of Zurich) concluded that the cysteine residues are bound by their thiolate groups to these metals in a tetrahedral configuration. Electron paramagnetic resonance and magnetic susceptibility studies of the cobalt derivative suggest that the metal sites are joined in clusters with some of the cysteinyl residues serving as bridging ligands between the metals, as exemplified by an adamantane-type structure.

Mammalian copper-metallothionein and the potential biological significance of its inducibility in some tissues by copper administration were discussed by I. Bremner (Rowett Institute, Aberdeen). The binding of copper to metallothionein differs from that of other metals and the metal to sulphur stoichiometry is much lower. The copper of anaerobically prepared metallothioneins is bound in the cuprous state in the form of Cu(I)-thiolate complexes. The binding mode is consistent with unusual luminescence properties observed in copper-metallothionein from Neurospora crassa (K. Lerch, University of Turiob)

That metallothioneins transfer metal to

J. Kägi is in the University of Zurich, T.L. Coombs and J. Overnell in the Institute of Marine Biochemistry, Aberdeen and M. Webb in the MRC Toxicology Unit, Carshalton.

^{*}A post-FEBS 2-day international meeting on metallothionein torganized by J. Overnell and T.L. Coombs) was held on April 4 and 5 at the University of Aberdeen, Scotland.

apo-metalloproteins was supported by K. Lerch and by U. Weser and H. Hartmann (University of Tübingen). They showed reconstitution of different copperdependent apoproteins with Neurospora and yeast copper-metallothionein respectively. However, no single function can be ascribed to metallothionein. M. Webb and K. Cain (MRC Tox cology Unit, Carshalton) demonstrated that in rats the protein can act as a mobile zinc and copper reserve in maintaining homeostasis or as a control agent for zinc and copper uptake in fetal and neonatal life stages. The detoxication role for controlling cadmium and mercury may well be a carry-over of this fetal mechanism into adult life.

Introducing the topic of metallothionein biosynthesis, R. Palmiter and D. Durham (University of Seattle) described experiments carried out on mouse metallothionein gene structure. Recombinant cDNA and genomic clones corresponding to mouse metallothionein-1 have been isolated and characterized. The DNA sequence indicates that this gene spans 1,100 base pairs with two intervening sequences (see Palmiter Nature 292; 267, 1981). The gene is regulated at the transcriptional level by heavy metals and less efficiently by glucocorticoid hormones both in vivo and in isolated cell lines.

Several cell lines that were selected for resistance to cadmium were shown to have amplified their metallothionein genes, allowing enhanced synthesis of this metalbinding protein. In an elegant study using DNA recombinant techniques, the regulatory portion of the mouse metallothionein gene was fused to the structural gene of thymidine kinase, rendering this enzyme inducible by Cd²⁺. Furthermore, evidence was presented that the inducibility of the mouse metallothionein gene is controlled by DNA methylation.

The application of high-pressure liquid chromatography to the assessment of homogeneity, structural investigations and the isolation of fragments from enzymatic and chemical cleavage of metallothioneins was described by K.J Wilson (University of Other communications emphasized the importance of these metalloproteins in the homeostatic control of specific metals not only in mammalian species but also in yeasts, marine arthopods, crustaceans, eels and sea-birds. From the significant developments that were reported in all fields it seems that the elucidation of the mechanisms of synthesis, degradation, gene regulation and of the structural arrangements at the metal-binding sites of the metallothioneins is 'just around the corner'.

Treating urea cycle defects

from Vicente Rubio and Santiago Grisolía

THERE is much interest in the treatment of inborn errors of the urea cycle. As pointed out by Smith¹ in her excellent review, the prospects for patients with deficiencies of this cycle are far better now than in the recent past. Therefore, we regret her omission of N-acetylglutamate synthetase deficiency and of N-carbamoyl glutamate as a therapeutic agent for this condition.

N-acetylglutamate, synthesized by N-acetylglutamate synthetase, is the physiological activator of mitochondrial carbamoyl phosphate synthetase. Deficiency of N-acetylglutamate synthetase should induce hyperammonaemia. The deficiency cannot be treated by administration of N-acetylglutamate because this compound is deacylated by cytosolic deacylases and it does not permeate the mitochondrial membrane. However, carbamoyl phosphate synthetase is also activated by analogues of N-acetylglutamate, such as N-carbamoyl glutamate2, which is resistant to deacylases and which, when injected into rats, can be found in the mitochondrial matrix of liver cells3.

Therefore, it is not surprising that

Vicente Rubio and Santiago Grisolía are at the Instituto de Investigaciones Citologicas de la Caja de Ahorros de Valencia, Valencia, Spain. Bachmann et al.⁴, who recently described the first case of hyperammonaemia due to N-acetylglutamate synthetase deficiency, found that N-carbamoyl glutamate is indeed extremely effective in the treatment of this condition.

As indicated by Smith, increases in the levels of N-acetylglutamate leading to greater activation of carbamoyl phosphate synthetase may improve control of ammonia levels in ornithine carbamoyl transferase, arginosuccinate synthetase and arginosuccinate lyase deficiencies and in partial defects of carbamoyl phosphate synthetase. Thus, although N-carbamoyl glutamate should be regarded as the specific treatment for N-acetylglutamate synthetase deficiency, its efficacy in these conditions should also be tested. N-carbamoyl glutamate may also be useful for patients with propionic methylmalonic acidaemias, for which decreased levels of N-acetylglutamate are postulated as a cause for the hyperammonaemia associated with these syndromes.

100 years ago

THE COMET OF 25 JUNE

The appearance of a large comet has afforded an opportunity of adding to our knowledge of these bodies by applying to it a new means of research. Owing to the recent progress in photography it was to be hoped that photographs of the comet and even of its spectrum might be obtained and peculiarities invisible to the eye detected.

It was obvious that if the comet could be photographed by less than an hour's exposure there would be a chance of obtaining a photograph of the spectrum of the coma, especially as it was probable that its ultra-violet region consisted of but few lines. In examining my photographs of the spectrum of the voltaic arc, a strong band or group of lines was found above H, and on the hypothesis that the incandescent vapour of a carbon compound exists in comets, this band might be photographed in their spectrum.

Accordingly at the first attempt a photograph of the nucleus and part of the envelopes was obtained in seventeen minutes, on the night of June 24, through breaks in the clouds. On succeeding occasions, when an exposure of 162 minutes was given, the tail impressed itself to an extent of nearly ten degrees in length.

I next tried by interposing a direct-vision prism between the sensitive plate and the object-glass to secure a photograph which would show the continuous spectrum of the nucleus and the banded spectrum of the coma. After an exposure of eighty-three minutes a strong picture of the spectrum of the nucleus, coma, and part of the tail was obtained, but the banded spectrum was overpowered by the continuous spectrum.

I then applied the two-prism spectroscope used for stellar spectrum photography, anticipating that, although the diminution of light would be serious after passing through the slit, two prisms, and two object-glasses, yet the advantage of being able to have a juxtaposed comparison-spectrum would make the attempt desirable, and, moreover, the continuous spectrum being more weakened than the banded by the increased dispersion, the latter would become more distinct. Three photographs of the comet's spectrum have been taken with this arrangement with exposures of 180 minutes, 196 minutes, and 228 minutes, and with a comparison spectrum on each. The continuous spectrum of the nucleus was plainly seen while the photography was in progress. For the present it suffices to say that the most striking feature is a heavy band above H which is divisible into lines, and in addition two faint bands, one between G and h. and another between h and H. I was very careful to stop the exposures before dawn, fearing that the spectrum of daylight might become superposed on the cometary spectrum.

It would seem that these photographs strengthen the hypothesis of the presence of carbon in comets, but a series of comparisons will be necessary, and it is not improbable that a part of the spectrum may be due to other elements.

REVIEW ARTICLE

A one-receptor view of T-cell behaviour

Polly Matzinger

Department of Pathology, University of Cambridge, Tennis Court Rd, Cambridge CB2 1QP, UK

The discovery of T cells and their behaviour has forced a re-evaluation of the immunological relationship between self and not-self. T cells seem to respond against foreign antigens only when the latter are in some form of association with self molecules encoded by the major histocompatibility complex. This has raised the question of whether T-cell recognition may depend on two separate receptors. I present here the case for a model of T-cell behaviour based on a single receptor.

"I shall always regard the differentiation between self and not-self as crucial to all immunological theory."—F. M. Burnet.

Consider an immune response to a virus infection. B cells respond by producing antibodies which bind to virus particles and neutralize them. T cells, however, do not deal directly with the virus itself but instead interact with other cells. For example, T helper cells collaborate with B cells in the production of antibody while T killer cells prevent viral replication by lysing virus-infected cells.

These differences in T- and B-cell function necessitate different modes of antigen recognition. Whereas the receptors on B cells (antibodies) should be able to bind free virus particles, the receptors on T cells should not. A T cell which, like antibody, chases down the bloodstream after virus particles is redundant, and it is not surprising that T cells do not bind viruses or other antigens alone. Instead they recognize two entities: the foreign antigen in question (which makes them antigen specific) and a special cell-surface marker (which targets them onto cells).

The cell-surface markers that serve as T-cell guidance molecules¹ constitute a set of highly polymorphic membrane glycoproteins encoded by the major histocompatibility complex (MHC). Some (K and D) are found on almost all cells of the body and are specifically recognized by T killer cells, while others (the I antigens) are found mainly on cells of the immune system and guide T helper cells.

The recognition of MHC products by T cells is extremely precise. They distinguish between the products of self and foreign MHC alleles and their response to foreign molecules has long been the major barrier to successful tissue transplantation. They also recognize allelic differences when using their own MHC molecules as guidance proteins. For example, a virus-infected animal of MHC type 'A' contains activated T cells capable of recognizing and destroying only virus-infected cells which express the A allele. This is known as 'MHC restriction' of T-cell recognition.

A key question raised by MHC restriction concerns the nature of the T-cell receptor. Do T cells bear two separate receptors each of which recognizes one of the two components (antigen and MHC) or do they bear one receptor which recognizes a complex of the two molecules? The two-receptor viewpoint, known as dual recognition, has the advantage of requiring no special assumptions about the two antigens. They can simply be molecules floating freely in cell membranes. However, it has the disadvantage of requiring many assumptions about the genetics, structure, development and affinity of T-cell receptors. Nevertheless most models of T-cell behaviour have been constructed on the basis of dual recognition ²⁻¹⁰.

It is time to reconsider the alternative known as the 'altered self' or 'interaction antigen' model¹¹⁻¹⁴. Based on a single T-cell receptor, it depends on one long-standing but difficult assumption about interactions between molecules in membranes. My

argument here is that this assumption still serves surprisingly well to explain the most important aspects of T-cell behaviour.

The assumptions

The assumption underlying the interaction antigen model is that T cells recognize neither antigen nor MHC molecules alone but rather molecular complexes composed of the two. This idea can be divided into two parts: (1) molecules in membranes can form associations (some transient, some more stable) which exhibit new antigenic determinants absent from the uncomplexed molecules; and (2) T cells are triggered to mature or differentiate only when they bind to MHC molecules on the surface of a specialized antigen-presenting cell.

Assumption (1)

Assumptions may be justified either because they make sense a priori or because of their ability to explain new data. I accept the idea of an interaction antigen purely on the basis of economy and predictive ability. First proposed in 1974, it has continued to explain many aspects of T-cell behaviour. A possible view of how such molecular interactions might occur was developed by Cohen and Eisen in 1977. They pointed out that, because cell membranes are essentially planar, the effective concentration of membrane molecules is exceedingly high. This high concentration generates a large number of molecular interactions, some of which will involve MHC molecules 15.

A molecule floating freely in a membrane conforms to the ionic, hydrophobic and electrostatic environment. The same molecule, when complexed (however briefly) with another, will find itself in an altered environment and may thus take on a different conformation. In complexes of MHC and antigen, three kinds of new determinant may be formed: (1) changes in the conformation of the antigen, (2) changes in the conformation of the MHC protein, and (3) new surfaces involving both antigen and MHC.

If such complexes exist, why are they not often detected in co-capping studies? Most such complexes, based on high concentrations rather than innately high affinity, will not be very stable and may be detectable only in certain conditions. Consider three interacting molecules: an MHC protein, an antigen and antibody directed against the antigen. Three equations govern their interactions:

MHC-antigen-antibody complex (3)

Depending on the antigenic determinant to which the antibody binds, the reaction depicted by equation (3) may predominate or not occur at all. The presence of an antibody directed against a determinant not available on the MHC-antigen complex will reduce the amount of free antigen and drive all three equations to the left, diminishing the number of MHC-antigen complexes. An antibody with greater affinity for the complexed antigen than for the free form will stabilize the complex, driving equation (2) to the right and co-capping the MHC and the antigen ¹⁶⁻¹⁹. These considerations should apply to T-cell receptors as well as to antibodies. In addition, the T-cell receptor, being membrane bound, may have a greater opportunity to achieve multipoint binding and thus further stabilize any molecular interaction to which it binds.

In principle, any molecule in the cell membrane should be able to interact with any other, yet the evidence is that T cells recognize only complexes that contain MHC molecules. This brings us to assumption (2).

Assumption (2)

Because recognition of MHC molecules is so important to T cells, it has been tempting to speculate that such recognition is genetically predetermined, that the germ-line genes code for a set of T-cell receptors directed specifically against MHC molecules. However attractive this assumption may seem, it cannot stand alone, and those who use it must explain (1) how T cells see non-MHC antigens, (2) how the gene pool manages to contain receptors able to bind new mutants in MHC molecules, and (3) how T cells choose from the gene pool those receptors which recognize the particular MHC allele(s) expressed by the body in which they live^{3-6,8,20}.

Because of these problems and, more importantly, because such a genetic bias is unnecessary, the interaction antigen model contains no such assumptions about the T-cell receptor gene pool and begins with a random repertoire (which may, in principle, contain receptors capable of binding any molecule alone or in combination with any other). How then are T cells restricted to recognition of antigen in the context of MHC molecules?

An early interaction antigen model¹¹ introduced the antigenpresenting cell as the determining factor in MHC restriction, proposing that T cells are selectively activated only when they bind to MHC molecules on the antigen-presenting cell surface (a concept generally accepted by all models of T-cell behaviour).

The general idea is that antigen-presenting cells participate actively in T-cell induction in two ways. First, they present antigens as well as MHC molecules to virgin T cells. Second, when a T cell binds to one of these MHC molecules, the antigen-presenting cell is induced to produce a differentiation signal. It is this differentiation signal which activates the T cell.

T cells should be able to bind in several ways to MHC molecules on the surface of antigen-presenting cells. Some will bind specifically to the MHC itself while others will bind to interaction determinants found on molecular complexes containing MHC. Like the antibodies discussed earlier, these latter may stabilize the complex, and the T cell will thus be treated like one which has bound free MHC. In general, any T cell which binds strongly to an MHC complex, no matter which part of the complex it binds, will be signalled to differentiate. Any T cell which binds any other complex or free molecule, failing to bind MHC, will not trigger the presenting cell and will not be activated. Thus, beginning with a random repertoire, one finishes with a functional set of T cells that are MHC restricted.

T-cell ontogeny and induction

Although all interaction antigen models are based on the same two assumptions, they differ in their development of specific points¹¹⁻¹⁴. In what follows I have tried to draw on those ideas which lead to the simplest overall view.

No assumptions were made about the germ-line genes coding for T-cell receptors. A simple idea would be that B-cell variable-region genes also code for T-cell receptors, but we can as easily start with a T-cell precursor population carrying any random set of specificities.

This repertoire of specificities must be modulated early in development to remove or inactivate T cells directed against self²¹⁻²³. Self tolerance is learned anew within each individual

and must involve at least two types of T cell: those specific for the self-MHC molecules alone and those specific for associations of other self molecules with self-MHC. It is unclear whether cells specific for isolated non-MHC molecules must be tolerized. Every potentially inducible cell must be tolerizable²⁴, but, as T cells specific for isolated non-MHC molecules fail to bind MHC, they are not inducible and should never be activated in the normal animal. However, were they to be activated by a cross-reactive complex of foreign antigen plus MHC, they could become autoreactive. One reason for supposing that such cells may not be tolerized is that it would require tolerance to have a different specificity from induction. Perhaps they form the basis of autoimmune disease. If so, one could predict that the destructive phase of some autoimmune diseases might not be MHC restricted.

Whether tolerance induction occurs in the thymus or in the periphery²⁵, and whether it occurs by mutation²⁰, deletion^{22,23} or suppression²⁶, parsimony suggests that the self antigens are presented by the same sort of antigen-presenting cell as those which present foreign antigens. The supposition then is that T-cell precursors are made tolerant when they bind to self-MHC molecules (or any complex containing self-MHC) on the surface of an antigen-presenting cell. This has the added attraction of allowing tolerance to occur to tissue antigens not normally intrinsic to cells of the immune system itself. Perhaps, as with B cells^{27,28}, an antigen recognition event may lead to tolerance in a young T-cell precursor and activation in a mature T cell.

Given a random repertoire depleted by self tolerance, several sorts of T cell will be available to bind to a foreign antigen X. Some will bind to X alone on the surface of the antigenpresenting cell but, failing to bind to MHC molecules, will not be activated. Others will bind in one of several ways to MHC-X complexes and will be activated. These T cells will retain their specificity and exercise their functions only when they encounter X in the same form as that with which they were activated, namely on the surface of a cell carrying the same MHC alleles.

MHC restriction

When Zinkernagel and Doherty first proposed 'altered self' recognition, the one thing known about MHC restriction was that T cells interacted only with syngeneic cells. The rules of T-cell behaviour are now better defined. How has the interaction antigen model held up?

Their original finding was that a mouse of MHC type A, immunized against an antigen X, contains activated T cells specific for targets carrying X+A and not targets carrying $X+B^{10,29-35}$. This simply reflects conservation of specificity—activated T cells respond best to the antigenic complexes with which they were primed. Because there are similarities between different MHC alleles as well as differences, X+A should have some determinants in common with X+B and a certain level of cross-reaction should exist. When T-cell responses are titrated far enough, such cross-reactions are usually seen $^{36-39}$.

It has since been shown that MHC-restricted T cells do not bind free MHC or free antigen. Competition experiments show that neither free MHC nor free antigen will block T-cell activity^{32,40-43}. Furthermore, to be bound by T cells, MHC and antigen must not only be cell bound, they must be together in the same cell membrane^{29,44,45}. This is, of course, predicted if T cells recognize only interaction antigens, whereas dual recognition models must explain it a posteriori.

A further problem for at least some dual recognition models is posed by T-cell reactions against cells bearing foreign MHC. These models explain MHC restriction by supposing that T cells cannot function unless both of their receptors are engaged, one receptor being specific for antigen and the other for self MHC. However if a target carries only foreign MHC alleles, the anti-self receptor should be useless and the T cell helpless. To deal with this, some dual recognition models suggest that alloaggression is a 'special' case in which T cells need bind only one of their receptors. In contrast, the interaction model does not invoke such 'special cases'—T cells need only one receptor

whether recognizing a foreign-MHC antigen or some modification of a self-MHC product.

For similar reasons, it is easier to accommodate 'aberrant recognition' in terms of the interaction antigen model. Since the original experiments on MHC restriction, it has become clear that T cells can recognize antigens presented with MHC molecules not found on their own tissues 1. These experiments are of course complicated by responses against the foreign MHC itself: an individual of MHC type A, immunized with antigen-presenting cells carrying MHC B and antigen X, makes such a strong response against B that it is virtually impossible to determine whether a response against antigen X also occurs. This complication can, however, be overcome by the removal of T cells reactive against B. In many experiments (but not all 12-54), removal of such T cells reactive to B has revealed a population which can recognize X + B. In short, an animal that is itself MHC type A carries T cells capable of recognizing X + B.

This is predicted by the interaction antigen models. Because the specificity of the functional T-cell population is selected only at the time of antigen encounter, there is nothing to exclude the recognition of X + B. An antigen-presenting cell carrying B can activate T cells as efficiently as a presenting cell carrying A. Some dual recognition models can also incorporate this finding^{2.8}, but most ignore it.

It is not surprising that the interaction antigen idea deals well with MHC restriction as it was originally created for precisely that purpose. How does it fare with other aspects of T-cell behaviour?

Immune response genes

Immune response (Ir) genes code for MHC proteins and determine whether an animal can respond to a particular foreign antigen. For example, a mouse of MHC type A may respond to a particular antigen X, whereas a mouse of MHC type B does not55-58. The two assumptions underlying the interaction antigen view of MHC restriction allow at least three ways of explaining the Ir phenomena. (1) Some MHC alleles are able to form complexes with X while others, because of their structure, may create inappropriate environments for complexes to form. If no complex forms, no T cell can be activated (reviewed in ref. 59). (2) For any complex of X with MHC, there may be some determinants for which there is no T-cell receptor gene 12,14,50 (3) The induction of self tolerance creates gaps in the functional T-cell repertoire. The adult animal, having lost the ability to respond against its own tissues, cannot respond against antigens which cross-react with those tissues 12,14

The first two explanations are straightforward. The third, while more complicated, can explain both MHC-linked and some non-MHC-linked immune response genes. It rests on the idea that a mouse of MHC type A is tolerant of many self components complexed with A. If an antigen X mimics self + A, the A-type mouse would be unable to respond to it. This does not mean that X itself must be identical to a 'self' component: it is the complex of X+A that is relevant. If X+A mimics any self + A complex, then an A mouse will not respond to X. However, an MHC B-type mouse may respond to X, implying that X+B carries some determinants not found on self + B.

How do these ideas stand up to our current understanding of Ir genes? An early model attributing nonresponsiveness to self tolerance predicted that responsiveness would be recessive on the dominant. However, the discovery of MHC restriction allows a re-examination of this idea. If strain A is a nonresponder to X and strain B a responder, then explanation (3) above states that X + A mimics self + A while X + B carries determinants which do not cross-react with self + B. The F_1 progeny of an $A \times B$ mating will be tolerant of both self + A and self + B and will be unresponsive to X + A, but they will see the non-cross-reactive determinants on X + B and thus responsiveness will be dominant.

The crucial point is that, to T cells, X+A and X+B are entirely different antigens. Tolerance to one has no implications

for tolerance to the other and thus T cells of both responder and nonresponder genotypes should 12,49,59 and do $^{6,61-64}$ respond to X if it is presented with a responder-type MHC allele.

Some immune responses are governed by two MHC genes (α and β) which exhibit a peculiar complementation pattern in that some alleles complement while others do not 65-69. (For example, if A, B and C are nonresponders, the $(A \times B)F_1$ may respond while the $(A \times C)$ and $(B \times C)$ do not.) If α and β code for the two chains of the Ia guidance molecules 70,71, then the simplest explanation is that a particular pair of α and β chains forms an Ia molecule which can associate in a recognizable way with X, while another pair cannot. The $(A \times B)F_1$ between two nonresponder strains will express the ineffective pair of Ia molecules of its parents $(\alpha^a \beta^a$ and $\alpha^b \beta^b$) and also two new types $(\alpha^a \beta^b$ and $\alpha^b \beta^a$). It is unpredictable whether a particular combination of α and β chains will form appropriate Ia molecules. However, some of the recombinant molecules may carry determinants which allow a response to X.

For some time all known MHC-linked Ir genes were located in the I region, provoking speculation that this might be the location of the T-cell receptor. However, Cunningham and Lafferty reasoned from the interaction antigen viewpoint that the known Ir genes mapped to the I region because the responses analysed had always been those of T helper cells, which use the I-region molecules as guidance molecules. They predicted that Ir genes for T killer responses would map to the K and D regions 11 —a finding 73 now accepted as a matter of course.

Some T-cell responses are controlled by genes outside the MHC as well as by MHC-linked Ir genes⁷⁴⁻⁷⁸. Whereas most models ignore these non-MHC immune response genes, the tolerance model is predicated on their existence and predicts their genetic behaviour. If a mouse of MHC type A is unresponsive to X because X + A cross-reacts with self + A, then the lack of response is controlled by two genes: one coding for MHC 'A', the other for the 'self' cell-surface molecule. Why then do most Ir genes map only to the MHC? I presume that this is due to the lack of polymorphism in the genes coding for other cell components. If the non-MHC surface molecule (such as a hormone receptor) has no alleles, then every strain carrying MHC 'A' will be tolerant of the same self + A complex and response to X will seem to be exclusively controlled by the MHC genes. However, if alleles of the self molecule do exist, then some strains may be tolerant of an allelic form of self + A which does not mimic X+A. In this way two mice may differ in their responses to X even if both carry the same MHC product. The critical prediction from the tolerance model is that, unlike the MHC-linked Ir genes, the non-MHC immune response genes should lead to dominant unresponsiveness. The progeny of a nonresponder (self¹+A) by responder (self²+A) mating will express and be tolerant of both self1 and self2 along with A. They should therefore be unresponsive to X.

Ir gene-controlled suppression: some mice appear to be unresponsive to an antigen because of suppression rather than deletion⁷⁹⁻⁸¹ and it has been suggested that this is inconsistent with cross-reactive self tolerance¹². However, I disagree. As self tolerance may be mediated or at least maintained by suppression^{82,83}, it is but a short step to suggest that nonresponsiveness due to cross-reactive self tolerance may also involve suppression.

Alloaggression

MHC molecules are themselves uniquely strong antigens^{84–88}. Two decades ago it was suggested that this strength reflected a high frequency of reactive lymphoctyes⁸⁶ and it is now known that as many as 10% of T cells can be specific for any foreign MHC molecule^{87,89–93}. Why is there a such high frequency of T cells specific for molecules which the individual meets only in artificial circumstances?

Although many explanations have been proposed^{2-6,8,11,20,94-99}, the interaction antigen model offers a new one¹³ which follows directly from the assumptions created for MHC restriction without any additions or special cases. The

argument is that if T cells from an MHC type-A mouse confront B-type antigen-presenting cells, they will recognize not only B but also all the complexes that B makes with the other molecules in the membrane. Thus the T cells are not responding only against the B antigens but against a very large number of antigenic complexes, and the frequency of reactive cells will be correspondingly high.

To analyse why this should occur let us return to self tolerance. A mouse is tolerant of its own MHC alleles and of all complexes they form with other self cell-surface molecules. It has no need and no opportunity to become tolerant of MHC type B either alone or complexed with other molecules. So, although mouse A is tolerant of its own components as seen with A, it will respond to these same components (as well as any new ones) associated with B. The result of immunizing with cells carrying foreign MHC molecules should thus be the massive and highly heterogeneous 100 response that is seen.

Does this interpretation account for other features of alloreactive responses? A single mutation at the MHC can elicit strong immune responses—this requires an explanation. It is known that in responses against conventional antigens, a single mutation at the MHC can profoundly change the T-cell response to the antigen associated with it 101. For example, T cells directed against X+A may not recognize X+A^M (the mutant). By analogy, T cells tolerant of self+A may not be tolerant of self+A^M. The mutant MHC will interact with normal surface molecules to generate a set of interaction antigens different from those formed by the parental MHC type. The mutant cells will thus present a large number of antigenic determinants to be recognized by parental lymphocytes.

If the majority of alloreactive T cells do not recognize MHC products except as interaction antigens with other cell-surface molecules, one would expect that purified MHC molecules would not interfere with alloreactions at any concentration. Although a few alloreactive cells should be directed against the foreign MHC molecules themselves, the effect of blocking them would be too small to be detected reliably. It has, indeed, been shown that purified MHC molecules do not block alloreactions^{41,42}.

Muddying the waters

So far I have shown how two assumptions deal with the principal features of T-cell behaviour. There is, however, one set of experimental results which has been used as evidence against the interaction antigen viewpoint. These are the experiments showing thymic 'bending'.

Homozygous MHC type-A mice which are irradiated and then reconstituted with $(A \times B)F_1$ bone marrow contain a peripheral set of F₁ T cells and also F₁ antigen-presenting cells that can present antigens in association with both A and B MHC molecules. The result of immunizing such a chimaera against antigen X should be the activation of two sets of T cells, one specific for X+A and the other for X+B. However, the experiments show that (A × B) T cells which have matured in an A animal respond preferentially to antigens associated with A, whereas maturation in a B animal confers a bias towards X+ $B^{6,62,102-105}$. Further testing showed that the organ responsible for this bias was the thymus $^{105-108}$. One interpretation has been that T-cell precursors are positively selected in the thymus 3-9,20 In an A thymus, T-cell precursors which bind to A would differentiate into functional T cells whereas those specific for B would not mature appropriately. Thus, even if X were later presented with both A and B, the response would be directed only against X + A.

Naturally such an interpretation is difficult for an interaction antigen model. There is no obvious way to select T cells for A+X or B+X in the absence of X. However, I disagree with the positive selection interpretation on two grounds. First, it depends on a special set of assumptions which are not required to explain other aspects of T-cell behaviour. Second, the 'aberrant recognition' experiments (see above) show that normal T

cells can recognize antigens presented with non-self MHC alleles. In fact, in one comparative study, T cells from $(A \times B) \rightarrow A$ chimaeras did not respond against virus + B, while normal A-type T cells, from which cells reactive to B had been removed, made good responses to virus + B^{51} . Both sets of T cells had matured in an A thymus, yet one was able to recognize X + B whereas the other was not.

So what is going on in the chimaeras? Obviously the thymus is having some effect on the T-cell repertoire long before encounter with antigen, but need it be a positive selection? Could it be the reverse?

Unlike the normal A mouse, an $(A \times B) \rightarrow A$ chimaera must be tolerant of B, yet, early on, its thymus contains only A-type antigen-presenting cells¹⁰⁹. How then does tolerance to B occur? There are broadly two ways in which tolerance may be induced. Natural self tolerance may occur either by deletion of self-reactive cells and/or by the induction of suppressor cells that function to suppress anti-self responses. A possible clue to the mechanism of tolerance in the radiation chimaeras comes from another type of $(A \times B) \rightarrow A$ chimaera: the classic neonatally tolerant mouse. Strain A mice which have been injected at birth with (A × B) cells are chimaeras 110,111 tolerant of B 112 and often exhibit immune responses 'bent' towards A113-115 Tolerance to B in these chimaeras can involve suppressor cells 116-119. Are the radiation chimaeras similarly suppressed 120? If this is the case, the suppression may extend to B+X (see refs 121, 122) while tolerance to A, occurring by the normal thymic route, allows a response to A + X.

Until these issues are resolved it does not seem appropriate to encumber the interaction antigen model with a new set of assumptions merely to explain a thymic positive selection which may not exist. The model predicts that the functional T-cell repertoire is the result of selection at the time of antigen encounter and I leave it at that.

Antigen encounters can be separated roughly into two sets: encounter with self antigens, which affects the repertoire by removing those specificities directed against self, and encounter with foreign antigen which increases the proportional representation of T cells reactive to the complex of that foreign antigen with MHC. If, unexpectedly, the thymic bias does turn out to reflect a positive selection for self MHC, then it will be time to act in accordance with current immunological practice—to add another assumption.

Recapitulation

The two basic assumptions are: (1) molecules in membranes interact to form new antigenic determinants, and (2) T cells are triggered when they bind to MHC molecules on an antigenpresenting cell (either for tolerance or reactivity).

T-cell development: (1) Pre-T cells enter the thymus and express receptors from a pool which may be as random as that of B cells (perhaps the same pool). (2) T cells capable of binding to MHC molecules on antigen-presenting cells in the thymus are inactivated, including T cells which recognize self non-MHC molecules in association with self MHC. All other T cells mature and peripheralize. (3) At the time of antigen encounter, T cells which bind to antigen in association with MHC molecules on the presenting cell are activated.

Ir genes: Three types of defect control immune responses: (1) the antigen cannot associate with the MHC molecule; (2) the T-cell receptor gene pool lacks a receptor for a particular interaction determinant; and (3) the complex of antigen + MHC mimics self.

Alloaggression: The high frequency of alloreactive cells exists because normal non-MHC membrane molecules associate with the MHC on foreign antigen-presenting cells to create a very large and heterogeneous set of antigens that in turn is recognized by a large and heterogeneous set of T cells.

Conjectures

A model is only as good as its predictions. The following predictions are not made by dual recognition models and are

Fourth, a mouse of MHC type A should be able to respond to

both self and non-self antigens complexed with MHC type B

If any of the following are true, then the model presented here is

wrong and cannot be saved with additional assumptions or any

special pleading. (1) If T cells which are MHC restricted at one stage (such as effector function) are found to be unrestricted at

an earlier stage (such as activation or tolerance). (2) If a somatic

cell hybrid of two T cells of different restriction specificities has

the mixed specificity, that is, if one parent sees X+A and the other sees Y + B and the hybrid sees in addition X + B and Y + A.

Refutations

therefore distinguishing characteristics of the single receptor/interaction antigen viewpoint.

First, it follows from assumption (1) that MHC-restricted antibodies should exist. If interaction antigens exist and can be recognized by T cells, they should be seen by B-cell receptors as well. MHC-restricted antibodies should be a small fraction of the total antibody made against any antigen and will often be missed; however, possible candidates do exist^{123,124}. It is the dual specificity of T cells which led to the suggestion that they express two receptors. If single antibodies can be MHC restricted, there should be no need to postulate two receptors for T cells.

Second, some T cells specific for MHC A associated with X should bind B+Y or even Y alone. There is no reason to expect that a new antigenic determinant will be unique to one particular complex. It has already been shown that some T cells specific for self MHC+X cross-react on allogeneic MHC, that is, A+X=B¹²⁵⁻¹²⁸. A type of cross-reaction which would not be predicted

by dual recognition models is A + X = B + Y (or A + X = Y). Third, some non-MHC-linked Ir genes⁷⁴⁻⁷⁸ should show dominant unresponsiveness (see the explanation of tolerance).

Effect of ions on the light-sensitive current in retinal rods

K.-W. Yau, P. A. McNaughton & A. L. Hodgkin

Physiological Laboratory, University of Cambridge, Cambridge CB2 3EG, UK, and Department of Physiology and Biophysics,
The University of Texas Medical Branch, Galveston, Texas 77550, USA

The effect of ions on the light-sensitive current of retinal rods was studied by sucking the inner segment into a tightly fitting capillary with the outer segment projecting into a flowing solution. This new method showed that the light-sensitive pathway, in which Na^+ is the normal carrier of current, has an ionic selectivity different from that of other known sodium channels. External calcium has a striking effect on the current, which increased about 20-fold when all calcium was removed. Reducing the sodium concentration gradient greatly prolonged the response to a flash of light, as would be expected if internal calcium blocks sodium channels and if light releases calcium which is subsequently extruded by a sodium-calcium exchange mechanism.

THE experiments described here were carried out with a new method which gives quantitative information about the effects of ions on the current generated by an isolated photoreceptor. The method is an extension of that developed by Baylor, Lamb and $Yau^{1.2}$ and in its usual form depends on sucking the inner segment of an isolated rod into a recording capillary while leaving the outer segment projecting into a flowing solution whose composition can be changed rapidly. This arrangement (Fig. 1a) allows one to examine the effects of substances on the light-sensitive pathways in the outer segment; similar experiments on the inner segment may be carried out by inverting the cell as in Fig. 1b. Light responses obtained with the two arrangements were of similar shape and size and of the same polarity with respect to the rod.

A piece of retina from a dark-adapted toad (Bufo marinus) was chopped into small pieces in Ringer's solution under IR light, yielding a preparation that consists of many detached outer segments, which did not give light responses, and a few fairly complete cells, that is, outer segments still attached to inner segments containing a nucleus but without synaptic endings. When the inner segment of such a cell is sucked into a closely fitting pipette containing Ringer's solution it gives currents of the usual form and magnitude for several hours.

In addition to changing the light-sensitive current, test solutions may set up a junctional current that arises from the small difference between the junctional potentials at the two boundaries of the test solution. Unlike the light-sensitive current, the junctional current did not change sign when the rod was inverted, nor was it much altered by replacing a complete rod by an inert outer segment. When the results were corrected for this junctional current, it was found that changing external ions altered the dark current but usually had little effect on the current in the presence of a bright light, which remained close to zero.

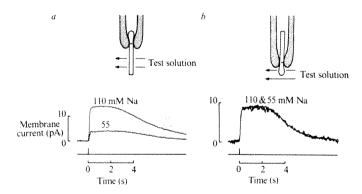

The records in Fig. 1 show that halving the sodium concentration round the outer segment reduced the light response to one-third but had no effect on the response when applied to the inner segment. This illustrates the difference between the two parts of the cell and shows that there was no appreciable leakage of ions through the tight seal at the mouth of the capillary.

Ionic selectivity of the light-sensitive channel

As expected from previous work³⁻⁹, replacement of sodium by choline in the solution bathing the outer segment abolished the light response in a rapid and reversible manner. Figure 2 shows the relationship between the maximum response and external sodium concentration with 1 mM Ca in the external solution. A similar curve is obtained with 0.1 mM Ca in the external solu-

tion, except that the currents are scaled up by a factor of 3-5 (see below).

We looked for an inverted response in the complete absence of external sodium but could detect no response of either polarity in sodium-free choline solutions containing the normal amount of external calcium (1 mM). This failure to see an inverted response may be due to (1) the recording limit of $\sim 0.1 \, \mathrm{pA}$, (2) the probable hyperpolarization when the dark current is cut off in low external sodium, (3) the possible closure of sodium channels resulting from the rise in internal calcium which might follow removal of external sodium¹⁰. The responses seen in sodium-free solutions containing 0 Ca–EGTA are discussed below.

a, Above, recording arrangement with the rod inner segment drawn into the Ringer-filled pipette and the outer segment exposed to test solutions. Membrane current was recorded with a current-to-voltage transducer connected to the pipette. Below, averaged responses to identical bright flashes in the presence of either 110 mM Na or 55 mM Na + 55 mM choline In plotting the traces the baseline has been shifted so that the dark levels superimpose. b, Experimental conditions similar to a, except that the rod outer segment was inside the pipette and the inner segment exposed to test solutions. Outward membrane current across the outer segment is taken as positive (upwards) in both cases; responses are low-pass filtered at 30 Hz (6-pole); temperature 19 °C. Time separation between recordings in a and b (which were obtained on the same rod) was ~2 h, during which the maximum response of the cell had declined somewhat. Light monitor trace below the responses indicated timing of 20-ms flash ($\lambda=500$ nm). The flashes delivered 37 photons μm^{-2} (unpolarized), corresponding to 740 photoisomerizations (Rh*) per flash for an outer segment with an effective collecting area of about $20~\mu\text{m}^2$. The Ringer's solution in all experiments contained (mM): NaCl, 110; KCl, 2.5; MgCl₂, 1.6; CaCl₂, 1.0; HEPES (neutralized with tetramethylammonium hydroxide to pH 7.6), 10; glucose 3. Test solutions were similar except for the specific substitutions stated. Calcium buffers were made with EGTA, HEDTA and Mg-EDTA to cover a range of 10^{-5} – 10^{-8} M Ca²⁺ using the stability constants in ref. 29. The seal resistance with the rod in position was 12 M Ω in a and 8 M Ω in b. In other experiments seal resistances varied between 5 and 15 MO.

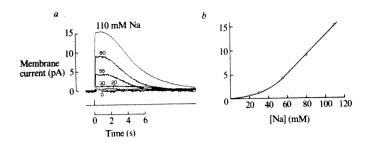

Fig. 2 Dependence of light-sensitive current on external sodium. a, Responses of an isolated rod to bright flashes (delivering 1,534 Rh* per flash) with different sodium concentrations bathing the outer segment. Temperature 19 °C. Choline was used as substitute in the low-sodium solutions. The 110 mM Na solution (Ringer) was applied between different low-sodium solutions and the response in a represents the grand average of 34 responses all within the range 14-16 pA. The other responses are averages over 3-10 flash trials. Note the prolongation of the plateau at external sodium concentrations < 55 mM. b, Plot of the response peaks in a versus external sodium concentration. 1 mM Ca²⁺ present throughout.

Lithium was able to substitute for sodium in carrying the inward dark current, but was less effective. Complete replacement of sodium with lithium reduced the current from 15.4 to 0.6 pA in a representative experiment. With a solution in which all but 20 mM of sodium had been replaced by choline the current was 0.56 pA. As 20 mM Na is almost as effective as 110 mM Li we conclude that the permeability ratio P_{Li}/P_{Na} is about 1:5 in these conditions. A similar ratio was also obtained with sodium present throughout. In the presence of 55 mM Na, replacing 55 mM choline with lithium caused an increase in current from 4.0 to 6.3 pA. Earlier in the same experiment an increment in sodium concentration from 55 to 80 mM caused an increase in current from 4.2 to 9.0 pA. Assuming that the current increase was proportional to the sodium increment in this concentration range (see Fig. 2), we calculate that 13 mM Na is equivalent to 55 mM Li, and therefore that the permeability ratio is 1:4.2. The permeability ratio was also not significantly affected by reducing the external calcium to as low as 1 µM even though in low calcium the dark current is greatly increased.

The other alkali cations behaved quite differently. With zero external sodium, application of 110 mM potassium, rubidium or caesium produced no detectable current in the presence of 1 mM Ca, but at lower concentrations small currents were observed. In 100 μ M Ca, tentative values of the permeability ratios were $P_K/P_{Rb}/P_{Cs}/P_{Na}=0.02:0.015:0.01:1.0$. In the presence of external sodium, however, potassium and to a lesser extent rubidium, but not caesium, actually reduced the existing dark current. In one experiment, increasing potassium from 2.5 to 20 mM, with sodium present as the main cation in both cases,

reduced the dark current to 36%. This effect cannot be attributed to potassium leaking into the pipette and depolarizing the inner segment because when the rod was inverted in the pipette and the same solutions applied to the inner segment, the current was reduced only to 75%. It therefore seems that external potassium and rubidium ions have some kind of blocking action on the inward sodium currents in the rod outer segment.

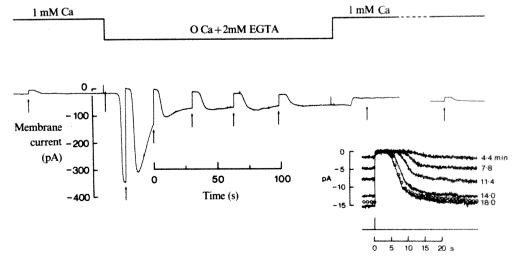

These results show that the sodium conductance in rods differs in its ionic selectivity from other known sodium conductances. In nerve, for example, lithium substitutes equally for sodium¹¹⁻¹³ and external potassium has no direct blocking effect¹⁴. It remains for future work to show whether the light-sensitive conductance is a pore or a carrier system.

Effects of external calcium on dark current

In agreement with Yoshikami and Hagins¹⁵, altering the external calcium concentration caused large changes in dark current and light response. In Fig. 3, 0 Ca plus 2 mM EGTA increased the dark current and light response from 15 to 340 pA. This large dark current, which depended on external sodium, was not maintained probably because the cell gained sodium and lost potassium. On restoring Ringer's solution, the light response often disappeared completely for a few minutes and when it returned it was smaller and much longer than normal. However, a full sized response was usually restored within 10-20 min or sooner if the exposure to 0 Ca was shorter. Details of the changes in response during recovery are given in the inset of Fig. 3. Evidence that the lengthening of response and reduction in photocurrent after a period in low calcium were caused by entry of sodium is provided by the facts that they occurred only if sodium was present during the period in low calcium, and they disappeared if the rise in dark current was prevented by exposure to a bright light during the application of 0 Ca.

Raising external calcium from 1 to 5 mM decreased the light-sensitive current to about one-quarter and lowering it from 1 to 0.1 mM increased the current by a factor of 3-6. In one rather complete experiment, replacing 1 mM Ca with 10 μM Ca increased the current from 20 to 170 pA whereas 0 Ca-EGTA gave 320 pA, both measurements being repeated twice. The initial effect of altering calcium concentration was to scale the quantal response in proportion to the dark current. In the above experiment, tests with weak flashes showed that the peak current produced by absorption of a single quantum was 0.1 pA in 5 mM, 0.35 pA in 1 mM and 2.5 pA in 10 µM Ca. The approximate proportionality between the quantal response and dark current indicates that the fraction of channels blocked by a single photon remains roughly constant in spite of the large increase which calcium reduction must produce either in the total number of sodium channels open in the dark or in the conductance of individual channels.

Fig. 3 Low-gain record showing the effect of removing external calcium on the photocurrent in a toad rod. Inward current is shown downwards from the level in bright flashes. Flashes each giving 5.2×104 Rh* were delivered at times indicated by arrows. Mg was present throughout at 1.6 mM, K at 2.5 mM and Na at 110 mM. Inset, details of the same experiment showing recovery of dark current and light response (unaveraged) in Ringer's fluid. Numbers give the time after restoring Ringer; open circles show the response before applying 0 Ca. Inward current shown downward from the level after bright flash, which remained constant during the recovery period.

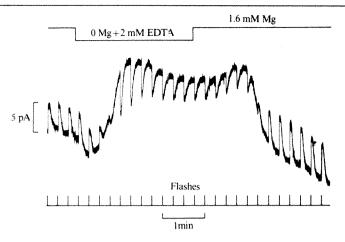

Fig. 4 Inversion of rod light response in 0 Mg and 0 Ca solution. Outward membrane current across the outer segment is upward. Solutions contained 110 mM choline chloride, 2.5 mM KCl, 0 Ca, 2 mM EGTA and 1.6 mM MgCl₂ or 0 Mg with 2 mM EDTA. The bright flashes, which elicited saturating responses, were estimated to give 6,500 Rh* in the outer segment. The solution change in this experiment was slower than in other experiments, with a time lag between change in tap position and solution change around the outer segment of about 0.5 min.

Experiments with a rapid flow system in which external calcium was changed from 1 to 5 mM and back showed that the restoration of dark current lagged behind the solution change at the pipette by ~ 1 s and that the restoration of dark current after reducing calcium occurred much faster than the return of current after a bright flash. The following values were obtained in two experiments with a particularly fast flow: time of solution change measured between 10 and 90% limits = 0.6 s; time for dark current to increase between the same limits after lowering $[Ca]_0$ from 5 to 1 mM = 1.6 s; time for dark current to increase between same limits after bright flash = 10 s. Another relevant comparison is that the maximum rate of increase of current on reducing calcium from 5 to 1 mM was 9 pA s⁻¹, whereas the corresponding value after a bright flash was 1.6 pA s⁻¹. In these experiments the speed of the solution change was obtained from the change in junctional current measured in the presence of a bright light.

The speed with which external calcium ions affect the sodium conductance is explained simply if they act directly on the outside of the membrane, but an internal action cannot be ruled out. If calcium ions act internally, as has sometimes been proposed¹⁶, one must elaborate the calcium transmitter hypothesis to accommodate the observation that the recovery of dark current after a bright flash is so much slower than the recovery when external calcium ions are reduced. One modification is to assume that calcium release continues after the light flash is over. Another is to suppose that calcium shuts channels, but that a more complicated process is involved in opening them again.

Light responses in the absence of external sodium

Using voltage recording, E. R. Griff, L. H. Pinto, B. L. Bastian and G. L. Fain (personal communication) showed that in solutions containing calcium buffered to 10⁻⁸ M with EGTA, replacement of sodium by choline did not abolish the response but gave a residual response of normal polarity. We have observed the same phenomenon when recording current but only if the choline-EGTA solution contained magnesium. With no magnesium we obtained an inverted response, that is, an outward dark current that was suppressed by light (Fig. 4). These magnesium-sensitive currents appeared only if the calcium concentration was less than ~1 µM. Their appearance might be explained if the effects of calcium removal on cation conductance are brought about by unmasking negatively charged sites which attract sodium and magnesium ions into or near the light-sensitive channel. Thus, if calcium removal created a negative potential well large enough to increase sodium permeability by 20, it should on a simple basis increase magnesium permeability by 400. The effect of magnesium removal in inverting the EGTA response has recently been confirmed in similar conditions with intracellular voltage recording (V. Torre, E. Pasino, M. Capovilla and L. Cervetto, personal communication).

Effects of alterations of external and internal sodium

Alterations in external sodium have a striking effect on the time course of the light response. Reducing the sodium concentration from 110 to 20 mM prolonged the response to strong and weak flashes (Fig. 5). It also made the cell more sensitive in the sense that low sodium increased the fraction of the maximum current suppressed by each absorbed photon. The correlation between time to peak and amplitude illustrated by the scaled responses in Fig. 5c is reminiscent of the desensitizing effects of background

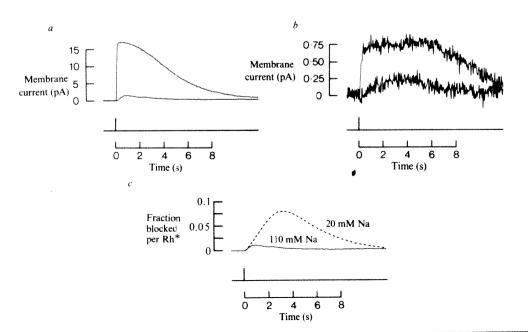

Fig. 5 Change in sensitivity and response time course in the presence of low external sodium, a. Averaged responses to bright and dim flashes in Ringer's solution (110 mM Na) before and after applying low sodium. Bright flash gave 1,660 Rh* and dim flash 8.1 Rh*. b, Averaged responses to bright and dim flashes in 20 mM Na. Bright flash gave 1,660 Rh* and dim flash 4.14 Rh*. Note the substantial prolongation of the responses. 1 mM Ca present throughout. c, Comparison of dim flash responses in 110 mM and 20 mM [Na]₀. Responses have been scaled to show the fraction of dark current blocked by one photoisomerization (Rh*). Response in low [Na]o (dotted curve) smoothed by eye.

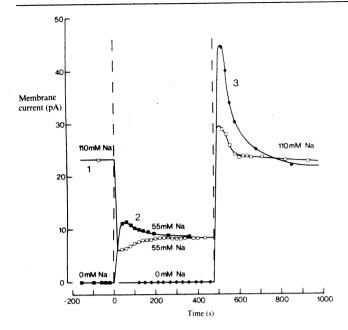

Fig. 6 Time course of change in response amplitude to bright flashes (1,660 Rh* per flash) with partial or complete replacement of external sodium by choline. 1 mM Ca present throughout. Note overshoot when sodium is increased and undershoot when it is decreased. Curve 1 ([]): [Na]₀ was 110 mM up to time 0, then 55 mM for 480 s and finally 110 mM again. Curve 2 (■): [Na]₀ was 0 from -480 s to time 0 and then 55 mM for 480 s. Curve 3 (♠); [Na]₀ was 0 from time 0 to 480 s and then 110 mM. The three curves were obtained consecutively on the same rod.

lights¹⁷, with an increase in sodium gradient being roughly equivalent to a rise in background light intensity.

The effects of external sodium on response duration can be explained if a flash of light releases calcium ions which are then extruded to the external solution by sodium-calcium exchange 18-22 A similar argument can account for the greatly prolonged responses seen in solutions in which external sodium is replaced by lithium.

Conditions which should increase internal sodium concentration, such as treatment with strophanthidin or previous exposure to low calcium (Fig. 3), also slowed the response to light flashes. This might be explained if internal sodium inhibited calcium transport across either disk or surface membrane.

The transient component in the response to changes in external sodium and calcium

A striking feature of the light-sensitive current is that after a change in external sodium or calcium the current does not approach its steady value monotonically but with an overshoot or undershoot of the kind shown in Fig. 6. An overshoot is seen when the dark current is raised by increasing external sodium or reducing external calcium and an undershoot when the dark current is decreased by ionic changes of the opposite kind. Figure 6 illustrates the effect of changing [Na]₀ at 1 mM Ca. The phenomenon is suggestive of a regulatory system in which sodium conductance varies inversely with internal sodium concentration. Such an effect might depend either on a direct inhibitory action of internal sodium or an indirect one, possibly mediated by the changes in internal calcium concentration that are likely to follow changes in internal sodium concentration²

For small perturbations from the normal condition in Ringer's solution, the half time with which the dark current returns is about 1 min, but shorter values and steeper-than-exponential return are seen for large overshoots (as in Fig. 6), and much longer half times and an S-shaped return after conditions likely to give a large increase in internal sodium, for example, after several minutes in 110 mM Na+0 Ca.

Possible effect of reducing internal calcium on sensitivity to light

Exposure of >10 min to solutions such as 20 mM Na, 0 Ca, 0 Mg, 2 mM EGTA, sometimes reduces the sensitivity of the rod by several orders of magnitude, perhaps because the disks in the rod have lost most of their calcium24. In these conditions the rod exhibits the phenomenon of 'superlinearity' in which doubling the intensity of a weak flash may increase the response by a factor of ≥10. This behaviour might be explained by assuming that (1) several calcium ions are required to block each sodium channel, (2) with normal calcium one photon releases sufficient calcium ions to block many channels in a small region, and (3) after treatment with 0 Ca-EGTA the disks contain so little calcium that several photons must be absorbed simultaneously in a small region to release enough calcium to block any sodium channels at all.

Conclusions

These experiments with isolated rods support the widely held view that sodium ions normally carry the light-sensitive current into the outer segment of vertebrate photoreceptors. They also show that the current which flows in normal conditions is only a small fraction of that observed in low calcium. When taken with the rapid effect of external calcium on sodium conductance the result may imply that the sodium pathway is closed for about 95% of the time by combination with external calcium ions, and that light blocks the pathway completely by closing the inside for 100% of the time. Such a mechanism might allow a finer grading of response and less dark noise than if there were fewer pathways open for most of the time.

The present experiments do not prove that calcium is the internal blocking agent released by light, as first suggested by Hagins²⁵, nor do they provide any information about the role of cyclic GMP, another potential transmitter26-28. They do, however, provide some indirect evidence for the calcium hypothesis, particularly when taken in conjunction with recent work on the light-activated extrusion of calcium 18,19. Thus, the strong influence of the sodium concentration gradient on the time course of the light response fits rather well into a scheme in which some of the calcium ions released by light are transported to the outside by exchange with external sodium. The powerful effects of calcium ions in suppressing sodium current when applied externally also makes it easier to assume that they may have a somewhat similar effect on the inside of the membrane.

We thank Professor D. A. Baylor for help in developing the method and Mr R. H. Cook for designing and building equipment.

The p21 src genes of Harvey and Kirsten sarcoma viruses originate from divergent members of a family of normal vertebrate genes

The Harvey and Kirsten strains of murine sarcoma virus encode enzymatically and serologically related p21 src proteins which are required for virally mediated cellular transformation. The genes in each virus encoding p21 show such extensive divergence from each other that cloned probes from these genes detect distinct sets of cellular genes in the DNA from several vertebrate species. These data suggest that cellular p21 sarc genes constitute a divergent family of vertebrate genes that can regulate the growth of cells.

THE Harvey and Kirsten strains of murine sarcoma virus (Ha-MuSV and Ki-MuSV) are replication-defective retroviruses that were isolated from independent mouse tumours induced by murine leukaemia viruses which had been passaged through rats 1,2. Ha-MuSV and Ki-MuSV are capable of both transforming fibroblasts in cell culture and inducing sarcomas and erythroleukaemias in susceptible mice3. The only known gene product of the viruses is a 21,000-molecular weight (MW) protein (p21) which is required for cellular transformation⁴ and is present at relatively high levels in virally transformed cells; a related but distinguishable p21 is constitutively expressed at low levels in normal cells of many vertebrate species⁵. Thus, p21 is a member of the class of normal cellular proteins whose coding sequences have been incorporated into the RNA genomes of various transforming retroviruses, such as Rous sarcoma virus⁶, Abelson murine leukaemia virus⁷ and feline sarcoma virus⁸. The phosphoproteins derived from these normal cellular proteins are required for transformation by their respective viruses and are ATP-using protein kinases⁹⁻¹¹. Viral p21 differs from the other kinases in that it specifically binds guanine-containing nucleotides and can transfer the γ-phosphate of GTP to a threonine residue on p21 (ref. 12).

The nucleic acid sequences of Ha- and Ki-MuSV are derived from both murine leukaemia virus and rat cellular DNA 13,14. In the 5.5-kilobase (kb) RNA genome of Ha-MuSV, which has been analysed in much greater detail than that of Ki-MuSV, the rat sequences (4.5 kb) have been divided into two components: (1) 1.0 kb in the 5' half of the genome representing the viral transforming (src) and p21-encoding gene¹⁵; (2) 3.5 kb derived largely, if not exclusively, from replication-defective, non-transforming, retrovirus-like sequences which are highly reiterated in rat DNA and which express themselves in some rat cells as '30S' RNA 16,17. Recently, using a molecularly cloned probe from the Ha-MuSV p21 src sequences, we have cloned two related cellular genes (sarc) from the rat¹⁸. These p21 sarc genes are distinct from each other in that one is colinear with the viral src sequences while the other has three introns in its coding sequence; nevertheless, with appropriate in vitro molecular reconstructions, both genes can induce cellular transformation mediated by high-level expression of strongly related, yet distinguishable, p21 sarc proteins18

The gross structure of Ki-MuSV is very similar to that of Ha-MuSV. The murine leukaemia virus components of these two viruses are highly related and their rat cellular components show extensive homology^{13,14}. However, RNA heteroduplex analysis has revealed segments of rat sequences in the 5' half of

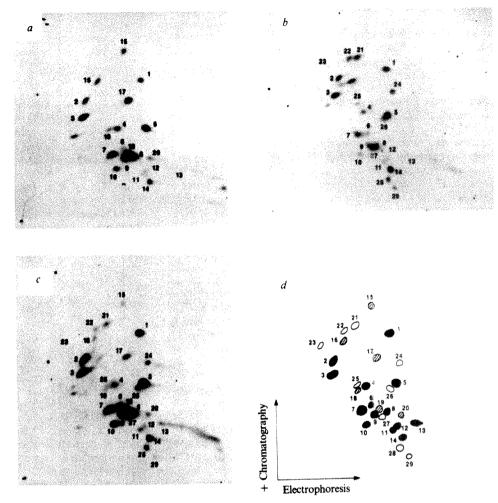

the two genomes which show little homology ¹⁴. Comparison of these heteroduplexing data with our recently published data suggests that this segment of poor homology in Ha-MuSV corresponds to the 1.0-kb src sequence which encodes p21. These results were quite striking as the p21s encoded by Ha-MuSV and Ki-MuSV had shown only minor serological and electrophoretic differences¹⁹, and we had not anticipated an apparently larger divergence in their nucleic acid coding sequences.

We have now analysed in greater detail the relationship between the p21s of Ha-MuSV and Ki-MuSV, and we have performed a more detailed structural comparison of the src genes of Ha-MuSV and Ki-MuSV using molecular clones of each virus. We have found that there is only a short segment [0.3 kilobase pairs (kbp)] of incomplete homology between their non-30S (that is src) components. Furthermore, using cloned fragments of each src sequence as radiolabelled probes for Southern blots of cellular DNA from a variety of species, we have shown that cellular sarc genes corresponding to Ha-src and Ki-src are detected as conserved genes in the DNA of several

	Table 1 Infecti	Infectivity of viral DNA clones		
DNA clones	Treat	ment	Foci per µg o	
H-1	Intact	in pBR322	6.0×10^{3}	
p-14	Self-lig		0	
HB-11	Self-lig		(7)	
KBE-2	Self-lig	,	(5)	
p-14+HB-11	Ligatio	,	9.0×10^{2}	
p-14+KBE-2	Ligatio		3.1×10^{2}	

The infectivity of the DNA preparations was tested through transfection onto NIH 3T3 cells using the calcium precipitation procedure 22,34. Clone H-1 DNA was used as a positive control. All other DNA clones were purified free of their pBR322 vectors by restriction endonuclease digestion (using enzymes from Bethesda Research Laboratories and New England Biolabs according to the suppliers' specification), agarose gel electrophoresis and electroelution³⁵. Purified inserts were ligated using T4 DNA ligase (New England Biolabs). DNA preparations (0.05-0.40 µg per dish) were transfected using calf thymus DNA as carrier (25 µg ml⁻¹), and foci of transformed cells were quantified from duplicate dishes. Representative foci were removed from the dishes using a cloning cylinder, so that the viral aetiology of the cellular transformations could be tested by p21 immunoprecipitation (see Fig. 5 legend for experimental details). The foci in parentheses are discussed in the text. Although these data are not related directly to the location of the viral src genes, we observed that HB-11 and KBE-2 DNA reproducibly induced low numbers of foci in these assays. However, when the DNA from such foci was analysed by Southern blotting, no new bands were detected homologous to the HB-11 or KBE-2 DNAs, and none of these foci expressed enhanced levels of p21. We do not understand the origin of these 'background' foci.

Fig. 1 Tryptic peptide analysis of p21 from cells transformed by Ha-MuSV or Ki-MuSV. MDCK dog cells transformed by Ha-MuSV, and C127 mouse cells transformed by Ki-MuSV, each in 60-mm dishes, were labelled for 22 h at 37 °C with 2 ml of lysine/arginine-free Dulminimal becco-Vogt modified essential medium supplemented with 2% dialysed fetal calf serum and 125 µCi each of ¹⁴C-lysine and ¹⁴C-arginine (Amersham, 350 mCi mmol⁻¹). Cells were lysed with 2 ml buffer containing 50 mM Tris-HCl, pH 8.0, 5 mM MgCl₂, 100 mM NaCl and 1% Triton X-100. After centrifugation for 30 min at 150,000 g, the cleared lysates were immunoprecipitated by antisera containing antibodies to Ha-MuSV p21 from tumour-bearing rats as described previously 4,19. The antigen-antibody complexes were precipitated by Staphylococcus aureus containing protein A. The precipitated proteins were analysed by discontinuous polyacrylamide gel electrophoresis in 0.1% SDS and were visualized by fluorography. The protein bands from the polyacrylamide gels, fixed diphenyloxazole, were excised for tryptic peptide analysis. Gel slices were swelled and digested in 1 ml of 0.1 M NH4HCO3 containing 20 g of DCC-treated trypsin (Sigma, Type X1) at 37 °C for 16 h. 20 µg of fresh trypsin were added and incubation continued for another 8 h. The eluted tryptic peptides were lyophilized twice and finger-

printed by electrophoresis for 70 min at 400 V in 30% formic acid on cellulose thin-layer plates (Schleicher and Schuell) followed by ascending chromatography in buffer containing *n*-butanol, acetic acid, pyridine and water (15:3:10:12 v/v). Peptide spots were visualized by fluorography, a, Ha-MuSV p21; b, Ki-MuSV p21; c, Ha-MuSV p21 mixed with equal c.p.m. of Ki-MuSV p21; d, interpretative sketching of c, where Ha-MuSV-specific, Ki-MuSV-specific, and common tryptic peptides are indicated by hatched, open and solid circles respectively.

vertebrate species. However, the individually conserved Hasarc and Ki-sarc gene(s) in each species are markedly divergent from one another, being present on different restriction fragments of DNA from that species.

Tryptic peptide analysis of Ha-MuSV and Ki-MuSV p21s

Our laboratory has demonstrated the close relationship between the Ha-MuSV and Ki-MuSV p21s by the criteria of serological cross-reactivity, electrophoretic mobility and guanine nucleotide-binding properties. To assess further, by an independent parameter, the relatedness between these src proteins and, indirectly, their genetic sequences, we performed two-dimensional tryptic peptide analysis on the p21s of Ha- and Ki-MuSV. To visualize every tryptic peptide except the most C-terminal one, virally transformed cells were labelled with 14C-lysine plus ¹⁴C-arginine. As shown in Fig. 1, 29 peptides have been resolved of which 6 are unique to Ha-MuSV p21, 9 are unique to Ki-MuSV p21, and 14 are shared by the two. Therefore, approximately two-thirds of Ki-MuSV and Ha-MuSV p21 peptides are shared, and this close, yet divergent, structural relationship has formed the basis for a detailed comparison of the genes encoding each viral p21.

Biological relationship between Ha- and Ki-MuSV molecular clones

Before studying the Ki-MuSV src sequences in detail, we sought biological evidence for the location of the Ki-MuSV src sequences relative to the well characterized Ha-MuSV src

region. The molecular cloning of the genomes of Ha-MuSV and Ki-MuSV has been reported. These clones, referred to as clone H-1 and clone 4 respectively 20,21 (Fig. 2), were derived from unintegrated closed circular DNA molecules isolated shortly after cell infection by the viruses. Consequently, the cloned sequences are circularly permuted with respect to their linear viral genomes. As our initial step towards analysing the Ki-MuSV src sequences, we investigated whether these transforming sequences indeed were in a position analogous to their location in Ha-MuSV, as the earlier data had suggested. An appropriate direct biological assay would be the testing of the transforming activity of subgenomic Ki-MuSV fragments in the calcium phosphate precipitation-mediated DNA transfection assay22. An initial problem in this determination was the inability of viral src sequences alone to induce efficiently formation of foci of transformed cells. The viral long terminal repeat (LTR) sequences, highlighted as a solid box on clone H-1 in Fig. 2, prove useful in overcoming this problem. The LTR, presumably containing an efficient promoter of viral RNA transcription, is an amalgam of sequences from both the 5' and 3' termini of the RNA genome, which are juxtaposed by transfer of nascent DNA between templates during reverse transcription²³. Ligation of LTR DNA to both the transforming sequences of Ha-MuSV²⁴ and Moloney-MuSV²⁵, as well as the cellular sarc sequences related to these two viruses 18,26, has resulted in enhanced transforming activity mediated by these DNAs. Accordingly, a large subgenomic Ha-MuSV fragment containing the LTR was cloned in pBR322 and designated clone p-14 (Fig. 2). The derivation of Ha-MuSV clone HB-11, which contains the entire viral src sequence, has been described18.

Ligation of these two clones at their common BamHI terminus resulted in efficient induction of transformed cell foci (Table 1). as expected. Therefore, a subgenomic Ki-MuSV fragment, residing in clone 4 in an analogous position to that of the HB-11 src clone in clone H-1, was cloned in pBR322 and designated clone KBE-2 (Fig. 2). Ligation of Ha-MuSV clone p-14 to Ki-MuSV clone KBE-2 at the BamHI terminus resulted in efficient focus formation (Table 1), confirming that clone KBE-2 did contain the Ki-MuSV src sequences. This result is consistent with published data which implicate the 5' half of the Ki-MuSV genome as required for transformation²¹. As expected, cells from foci induced by HB-11 or KBE-2 DNA ligated to the LTR fragment contained markedly elevated levels of p21 (data not shown). These results indicate that the viral p21 src genes of Ha-MuSV and Ki-MuSV are located in the same region of each respective viral genome.

Fine structural comparison of Ki- and Ha-MuSV src genes

Having confirmed the general location of the src sequences within the Ki-MuSV genome, we then compared these sequences with their Ha-MuSV counterparts. Clones KBE-2 and HB-11 were hybridized for heteroduplex analysis (Fig. 3, d-f). The 1.1-kbp segment '11+8+12' (Fig. 3f) in clone HB-11 represents precisely the published location and size of the Ha-MuSV src sequences relative to the 5'-terminal BamHI site in the clone ^{15,27}. Similarly, segments '6' and '10' (Fig. 3f) in clone HB-11 coincide with the reported location of rat 30S sequences. Heteroduplexing of clone KBE-2 to the rat 30S clone shows that segments '1' + '3' (Fig. 3c) correspond to the rat 30S sequences and segment '2' represents sequences specific to Ki-MuSV. Segments '7–9' in Ki-MuSV DNA (Fig. 3f) correspond to the Ki-specific segment '2' in Fig. 3c, and segment '8'

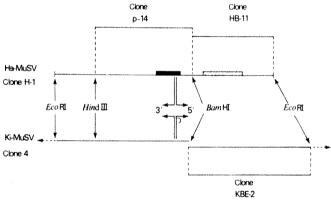

Fig. 2 Structural relationships among the viral clones. Ha-MuSV and Ki-MuSV RNA genomes had been molecularly cloned from preintegration circular DNA forms. Advantage was taken of the fact that retroviral RNA is reverse-transcribed after cellular infection into closed circular double-stranded DNA. Based on the uniqueness of particular restriction endonuclease sites, unintegrated viral DNA was purified from the Hirt supernatant of infected cells, cleaved with EcoRI (Ha-MuSV) or BamHI (Ki-MuSV), and cloned at these respective restriction sites in pBR322. (Ha-MuSV DNA originally had been cloned in λ gtWES · λ B³⁶ but subsequently was recloned in pBR322.) Consequently, Ha-MuSV clone H-1 and Ki-MuSV clone 4 are circularly permuted with respect to their RNA genomes, such that the termini of the genomes are juxtaposed in the DNA clones. The 5' and 3' halves of the viral genomes are demarcated as indicated on the DNA maps. The subgenomic fragments p-14, HB-11 and KBE-2 were derived from their respective parental clones by double digestion with the indicated restriction endonucleases, preparative gel electrophoresis and molecular cloning at the appropriate sites in pBR322. Clone p-14 contains the LTR sequences (solid box) which have a promoter-like sequence of the same 5'-3' polarity as the viral genome³⁷ and which significantly enhance the transformation efficiency of viral src genes. Clone HB-11 (ref. 18) contains the Ha-MuSV transforming sequences (cross-hatched box).

in Fig. 3f is homologous to a portion of the Ha-MuSV src region. Therefore, a 1.75-kbp segment in Ki-MuSV DNA, corresponding to segment '2' in Fig. 3c, contains the Ki-MuSV src sequences.

These heteroduplexing data have confirmed and extended the earlier RNA-DNA heteroduplexing experiments¹⁴ and have specified the location of *src* within Ki-MuSV DNA by virtue of its partial homology to Ha-MuSV *src*. In particular, our measurements of the heteroduplexes between these cloned DNA fragments can be combined with restriction endonuclease mapping data to clone a Ki-MuSV-specific fragment. To this end, we have developed a detailed restriction endonuclease map of clone KBE-2 and have compared it with the published map of clone HB-11, with the heteroduplexing data superimposed on the maps (Fig. 4). Note several features in this comparison: (1) virtually every site in the rat 30S DNA sequences (open box) of the clones is present in both Ha-MuSV and Ki-MuSV; (2) there is a complete site mismatch in the respective *src* sequences; (3) the location on clone HB-11 of the Ha-MuSV-specific (that is,

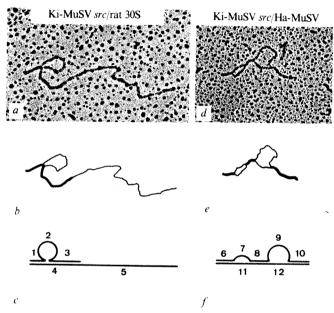

Fig. 3 Heteroduplex analyses of Ki-MuSV src, Ha-MuSV src and rat 30S DNA molecules. Heteroduplexes were prepared as described previously ^{27,38}. Briefly, a mixture of linear DNA molecules (each at a concentration of 4-6 µg ml⁻¹), freed from their cloning vectors by restriction endonuclease digestion and preparative gel electrophoresis, was denaturated by incubation in 0.1 M NaOH for 10 min at 22 °C. The solution was neutralized by the addition of 1/5 volume of 1 M Tris-HCl, pH 7.0. Deionized formamide was added to a final concentration of 50% and renaturation was permitted by incubation for 30 min at 22 °C. Heteroduplexes were mounted for electron microscopy after spreads on a hypophase of 18% formamide. The lengths of singlestranded Φ X174 (5,375 bp) and double-stranded SV40 (5,240 bp) circular DNA molecules were determined in separate experiments in similar spreading conditions to obtain a conversion factor for obtaining measurements of single- and double-stranded regions of the heteroduplexes. We calculate from these experiments that 1 μ m contour length of double-stranded DNA = 3,080 bp, 1 μ m single-stranded DNA = 3,040 bp. Electron micrographs (\times 54,000) are a, heteroduplex of Ki-MuSV fragment (clone KBE-2) and rat 30S DNA (clone 27A, which was cloned at the SacI site in λ gtWES · λ B²⁷) and d, heteroduplex of Ki-MuSV (clone KBE-2) and Ha-MuSV (clone HB-11) fragments. Interpretative tracings of the heteroduplexes are shown in b and e. Schematic representations (c, f) are based on the measurements of > 15 molecules. Contour lengths (in kb) were as follows: $1 = 0.40 \pm 0.02$, 2 = 1.75 ± 0.10 , $3 = 1.02 \pm 0.06$, 1-3 = Ki-MuSV clone, 2 = Ki-MuSVsrc, $4 = 1.50 \pm 0.08$, $5 = 3.83 \pm 0.33$, $4-5 = rat\ 30S$, $6 = 0.27 \pm 0.03$, $7 = 0.52 \pm 0.06$, $8 = 0.34 \pm 0.08$, $9 = 1.18 \pm 0.14$, $10 = 0.71 \pm 0.05$, $11 = 0.33 \pm 0.07$, $12 = 0.44 \pm 0.11$, 6-10 = Ki-MuSV clone, $7-9 = 0.00 \pm 0.00$ Ki-MuSV src, 6+8+10+11+12 = Ha-MuSV clone, 11+8+12 =Ha-MuSV src.

free of rat 30S) subgenomic fragment BS-9 (ref. 15) approximately circumscribes the region of cross-homology between Haand Ki-MuSV src. (solid box).

Pursuing this latter point, we performed Southern blot hybridization with ³²P-labelled BS-9 (Ha-specific) DNA as probe and were struck by its virtual lack of hybridization to clone KBE-2 (data not shown). We questioned whether this could be a function of differences in the relative stringency of hybridization conditions in the heteroduplexing and the Southern blotting procedures. Using the recently described formamide hybridization conditions which enable Southern blots to be hybridized under various levels of stringency²³, we found that ³²P-BS-9 and Ki-MuSV src hybridized well only in 'non-stringent' conditions (data not shown). This lack of reactivity of the two src sequences in stringent conditions suggests that a Ki-MuSV-specific probe might be isolated free not only of 30S RNA sequences but also of Ha-MuSV cross-reactivity in stringent conditions.

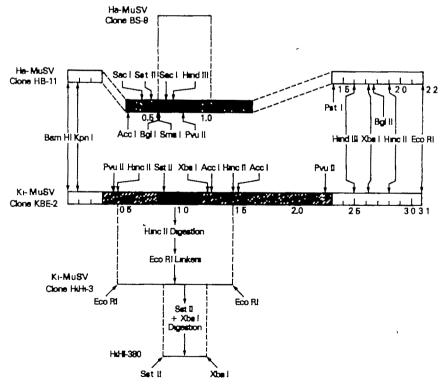

Detection of Ki-MuSV as distinct from Ha-MuSV sarc sequences in cellular DNA

Our approach to the development of a Ki-MuSV src probe depended on the probe being completely free of rat 30S sequences, insofar as these genes related to 30S are highly reiterated in rats and, to a lesser extent, in mice. Therefore, based on its lack of hybridization to cloned rat 30S DNA, a 1.0-kbp fragment of clone KBE-2 DNA was cloned in pBR322 (clone HiHi-3, Fig. 4). For use as a Ki-MuSV src-specific probe, a fragment of clone HiHi-3 was purified by preparative gel electrophoresis (HiHi-380, Fig. 4). We then used both the Ha-specific and Ki-specific DNAs as radiolabelled probes for Southern blots of high-molecular-weight DNA from cells of various species (Fig. 5). As biological controls for the specificity of the src probes, we performed hybridizations to EcoRI-digested DNAs from NIH 3T3 mouse cells infected with the

Fig 4 Detailed structure of Ha-MuSV and Ki-MuSV transforming sequences. A detailed restriction endonuclease map, on a scale demarcated in kbp, was developed for Ki-MuSV clone KBE-2. The detailed map of Ha-MuSV clone HB-11 is reproduced from the published map of the complete Ha-MuSV genome clone H-1¹⁵. Superimposed on these maps are the heterduplex data of Fig. 3. The open box represents common rat 30S RNA sequences; the solid box represents sequences shared by Ha-MuSV and Ki-MuSV but not rat 30S RNA; the hatched boxes represent sequences unique to either Ha-MuSV (lefthatched) or Ki-MuSV (right-hatched). Note the discontinuity of scale on clone HB-11 (dotted lines), drawn to compensate for the size differential between the Ha-MuSV- and Ki-MuSV-specific (hatched) sequences. details of the derivation of Ha-MuSV clone BS-9 have been published elsewhere¹⁵. To derive cloned sequences as a specific probe for KI-MuSV, we sought a fragment of clone KBE-2 which would not hybridize to rat 30S RNA sequences. Accordingly, singly and doubly restricted fragments of clone KBE-2 were electrophoround, blotted and hybridized to ³²P-labelled clone 27A DNA. A *HircII*—*HircII* fragment (map positions 0.4-1.4) was purified by preparative gel electrophoresis, and after blunt-end ligation of EcoRI linkers (Collaborative Research) to the DNA, molecules various rat-derived sarcoma viruses. The Ha-specific probe, hybridized to EcoRI-digested DNA from cells non-productively transformed by Ha-MuSV, detected an additional band compared with control cell DNA which was not detected by the Ki-specific probe (data not shown). Conversely, the Ki-specific probe, but not the Ha-specific probe, detected an extra band in EcoRI-digested DNA from cells non-productively transformed by Ki-MuSV (Fig. 5a and b, lanes 6).

A third cell line studied was NIH 3T3 cells transformed by the rat sarcoma virus (RaSV). This virus, whose entire genome is rat derived, was isolated after in vitro co-cultivation of two lines of rat cells²⁹. The only known gene product of RaSV is a 29,000-MW protein³⁰ which is closely related to Ki- and Ha-MuSV p21s in terms of common methionine-containing tryptic peptides as well as serological cross-reactivity³¹. When blots of EcoRI-digested DNA from RaSV-transformed NIH 3T3 cells were hybridized with the Ha-MuSV and Ki-MuSV src probes, an extra band relative to control cells was detected only with the Ha-specific probe, not the Ki-specific probe (Fig. 5a and b, lanes 5). These results demonstrate that the RaSV transforming sequences are more closely related to those of Ha-MuSV than to those of Ki-MuSV.

Having confirmed the specificity of these src probes, we then tested DNAs of rat, chicken, human and mouse for cellular p21 sarc sequences related to the viral src probes. It can be seen that the Ha-specific probe detected one or two bands in each of these EcoRI-digested DNAs (Fig. 5a, lanes 1-4). The Ki-specific probe detected one to three bands (Fig. 5b, lanes 1-4) distinctly different from the corresponding Ha-specific bands. The exceedingly weak hybridization of the Ki-specific probe to the 2.1- and 4.2-kbp chicken DNA fragments (Fig. 5b, lane 2) suggests that the normal cellular sarc sequences related to Ki-MuSV, having diverged more rapidly in chickens, are not as broadly conserved evolutionarily as are the Ha-MuSV sarc sequences.

were digested with EcoRI, purified free of linker monomers by Sepharose 2B (Pharmacia) chromatography and cloned at the EcoRI site of pBR322. This clone is designated Ki-MuSV clone HiHi-3. When it was used as a radiolabelled probe for Southern blots of cellular DNA sequences, innumerable bands were detected in rat DNA, even though one to three bands were detected in DNA from other species (data not shown). The origin of this redundancy with respect to rat DNA was unclear, although it could have represented rat 30S sequences present in clone HiHi-3 yet missing in the rat 30S clone which we had used to define HiHi-3. Nevertheless, we sought a fragment of clone HiHi-3, which would be 'single copy' in rat DNA, by trimming the clone HiHi-3 insert. To prepare such a fragment, the clone HiHi-3 viral insert was digested with SstII and the 0.6-kbp fragment purified by preparative gel electrophoresis. This fragment was digested with XbaI, then the 0.38 kbp fragment (HiHi-380) was purified by preparative gel electrophoresis.

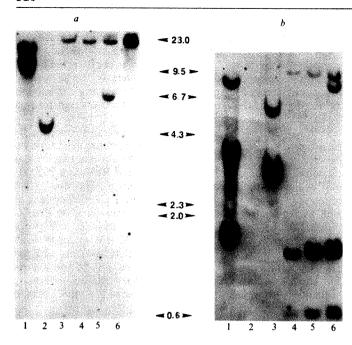

Fig. 5 Southern blot analysis of restriction endonucleasedigested high-molecular-weight cellular DNA. 50 µg of cellular DNA, prepared by established procedures³⁹, were digested for 16 h with 100 units EcoRI, electrophoresed, blotted and hybridized (in the 'stringent' conditions described in Fig. 4 legend) to either of two 32 P-labelled DNA probes (1.5×10⁷ c.p.m.). a, 32 P-labelled BS-9 (Ha-specific) DNA. b, 32 P-labelled HiHi-380 (Kispecific) DNA. Sources of high-molecular-weight DNA were: 1, FRE rat cells; 2, chicken cells; 3, human cells; 4, uninfected NIH 3T3 cells; 5, NIH 3T3 cells transformed by the rat sarcoma virus; 6, NIH 3T3 cells transformed by Ki-MuSV. The arrows indicate the positions of 32 P-labelled $\lambda/HindIII$ DNA markers (length in kbp). Panel a, lane 1 portrays the two rat cellular sarc genes related to Ha-MuSV src, as has been reported elsewhere 18. The hybridizing bands represent the intron-containing (20 kbp) and colinear (13 kbp) forms of Ha-sarc.

Discussion

The relationship between Ha-MuSV and Ki-MuSV is a more complex one than had been thought previously. Minor serological and electrophoretic differences between the viral p21s had suggested that the respective src proteins were merely variants of one another and were derived from the same cellular p21 sarc gene. This conclusion was consistent with the ability of these viruses to induce similar diseases in rodents and morphologically similar cellular transformants in vitro. The data presented here clearly demonstrate that the Ha- and Ki-MuSV src sequences are derived from distinct cellular p21 sarc genes. On the basis of the heteroduplexing, hybridization and tryptic peptide data, we deduce that there are two domains within the genes coding for the respective viral p21 molecules. One of these domains represents sequences unique to each p21 gene, sequences that are a subset of the hatched region of the viral genomes in Fig. 4. The other domain represents sequences shared by both the p21 molecules, as indicated by the solid box in Fig. 4. Assuming that these common sequences are entirely coding sequences, their length (0.35 kbp) would contain the genetic information for ~11,000 daltons of polypeptide chain, that is, one-half of the p21 polypeptide. Moreover, the ability of ³²P-Ha-specific DNA to hybridize to Ki-MuSV src in non-stringent but not in stringent conditions suggests that the Ki-common and Ha-common sequences are approximately 10-15% divergent. Most of this divergence would involve 'wobble-codon' changes and other nucleotide changes resulting in conservative amino acid substitutions, such that >50% of the tryptic peptides remain shared between the two viral p21s. It seems likely that these common sequences account for the serological cross-reactivity, guanine nucleotide-binding capacity and common biological potential (transformation) of the viral p21s. Apparently this represents the selection pressure for the conservation of the p21 amino acid sequences during the evolution of Ha-MuSV and Ki-MuSV p21 genes. Furthermore, our preliminary nucleotide sequence analysis of Ha-MuSV places these common sequences in the 5' half of the polypeptide chain (unpublished data). At this point, we can only speculate that the sequences unique to either Ha-or Ki-MuSV p21 contribute to as yet undiagnosed differences between the proteins.

Access to the contract of the

Our laboratory has demonstrated the expression of low (relative to cells transformed by Ha- or Ki-MuSV) levels of p21 in normal cells from a wide variety of species, and our Southern blots of various cellular DNAs have shown the broad evolutionary conservation of both Ha- and Ki-MuSV cellular genes. Given the presence of multiple related, yet distinct genes, are all or only some of the cellular genes being expressed in different cells? We have shown that rat DNA has two genes homologous to Ha-MuSV src: one is apparently colinear with p21 src while the other has three introns in its coding sequence (it is likely that one of these genes is the progenitor of the putatively transformation-specific p29 of the third rat-derived sarcoma virus RaSV). Both genes are fully functional, as each is capable of causing cellular transformation after DNA transfection. These transfections also have demonstrated that elevated levels of a normal cellular protein are sufficient to cause cellular transformation. With respect to homology to Ki-MuSV src, blots of EcoRI-digested rat DNA have three prominent bands, while blots of rat DNA digested with other restriction endonucleases have two to three major bands (unpublished data). These data suggest that there may be two Ki-MuSV cellular sarc genes in the rat, thereby making a minimum total of four rat genes capable of encoding a constitutively expressed p21. As there has probably been selection pressure favouring the retention of this entire family of p21 genes, it would be important to determine which of the genes is expressed in different rat cells. With respect to mouse cells, we have recently reported that a line of undifferentiated haematopoietic cells expresses higher levels of p21 than do Ha-MuSV or Ki-MuSV-transformed cells³², and we wish to determine which gene is encoding this p21. The structures of the various cellular and viral p21 polypeptides and their in vivo expression should elucidate functional differences among the various p21s. For example, there may be a tissue- or differentiation-specific pattern of expression among the genes, as in the globin gene family³³. By analogy to fetal and adult forms of globin, each distinct p21 might possess unique biochemical properties pivotal to its normal differentiation-related physiological role.

We thank Ralph Shober and Jean Maryak for technical assistance and Lorraine Shaughnessy for preparation of the manuscript.

A reinvestigation of the role of the grey crescent in axis formation in Xenopus laevis

J. Gerhart*, G. Ubbels*, S. Black*, K. Hara* & M. Kirschner*

Gravitationally induced displacements of the contents of the frog egg can predictably determine the orientation of the subsequent dorsal-ventral axis of the embryo, regardless of the original position of sperm entry or of the grey crescent. In certain conditions, these displacements in the egg can also lead to the formation of a second axis, that is, to twinning. The previously reported ability of grafts of grey crescent cortex to induce secondary axes in recipient eggs is interpreted here as an unrecognized twinning effect of gravity. Our results lead us to question the classic interpretation of the grey crescent as a dorsal determinant in amphibian development.

The unfertilized egg of most frogs and salamanders is organized with radial symmetry about its animal-vegetal axis. The embryo, however, has clear bilateral symmetry organized along anteriorposterior and dorsal-ventral axes. Early embryologists recognized the following events in the establishment of the dorsalventral axis¹⁻⁵: (1) a single sperm randomly enters the animal hemisphere, giving the egg its first bilateral symmetry; (2) before first cleavage, the egg forms a grey crescent, a region of reduced pigmentation in the animal hemisphere which, in the case of the frog egg, is opposite the side of sperm entry; (3) at gastrulation, about 15 cleavages later, the blastopore appears first at the lower limit of the surface region previously occupied by the grey crescent; and (4) dorsal structures of the embryo originate from the grey crescent region of the egg. As reported by Spemann and Mangold^{5,6}, the gastrula contains in the dorsal blastopore lip a group of cells which induce neighbouring cells to undergo dorsal development and are themselves incorporated into dorsal structures. Thus, the dorsal regions of the embryonic axis owe their location to the position of these inducer cells, the Spemann organizer, while ventral development occurs where the organizer is absent.

As the Spemann organizer region is so clearly responsible for the 'dorsalization' of the gastrula and neurula, the grey crescent, its topographical precursor, has been ascribed the capacity to generate the organizer. The most detailed proposal for the grey crescent's role is found in the cortical field hypothesis of Dalcq and Pasteels^{1,7}: the developmental fate of each egg region is said to derive from local values of two kinds of quantitative material gradients, the first a cortical gradient centred in the grey crescent at the egg surface, and the second, an internal cytoplasmic gradient oriented in the vegetal to animal direction following the concentration of yolk platelets. The blastopore and organizer would arise much later at the site where the combined value of the gradients is greatest. The two gradients were said to be distinguishable experimentally by their response to gravity or centrifugation, since the yolk platelets, but not the cortical materials, were expected to rearrange easily in the egg.

Although Pasteels¹ devised tests of this hypothesis involving rotation and inversion of eggs at the time of grey crescent formation, his results were rather ambiguous and have been generally neglected compared with the direct, dramatic support of Curtis8, who reported that the dorsalizing activity of the grey crescent cortex was transplantable. He removed a piece of grey crescent cortex from a donor egg of X. laevis shortly before first cleavage and grafted it into the equatorial surface of the prospective ventral side of a recipient egg at or close to first cleavage. In all 11, eggs receiving cortex from the crescent region double embryonic axes developed, one supposedly from the resident crescent region and one from the transplanted crescent region. Thus, the grey crescent cortex was concluded to be a dorsalizing locus, which preserved its activity on transplantion.

More recently, Nieuwkoop and co-workers^{3,9,10} obtained experimental results which contradict a strict cortical gradient hypothesis. They found that at the mid-blastula stage, the potential for dorsal development is carried by a group of cells in the vegetal hemisphere that are not topographically superimposable with the grey crescent. These vegetal cells induce the Spemann organizer to form in adjacent animal hemisphere cells, coincidentally in the grey crescent region. Furthermore, recent fate maps of X. laevis indicate that, contrary to earlier conclusions, the cells of the Spemann organizer do not derive from the grey crescent cortical area of the egg but from deeper cytoplasmic regions 11.12. Because of these discrepancies, we have repeated and extended for X. laevis several of the classic experiments on which the importance of the grey crescent rests.

Topographical relationship of sperm entry, grey crescent and blastopore in X. laevis

Shortly after fertilization, a small amount of pigment accumulates around the sperm entry point (SEP) in the animal hemisphere, producing a dark spot¹³. Approximately mid-way in the period from fertilization to first cleavage, the grey crescent appears on the side of the animal hemisphere away from the SEP, as a region of lighter and more granular pigmentation¹³. In \sim 90% of eggs, the crescent forms in the sector 135°-180° from the SEP14, but the broadness and diffuseness of the crescent in X. laevis preclude more accurate measurement of its position relative to the SEP or blastopore. As the SEP can be very accurately localized, we have marked eggs with Nile blue at an equatorial position (that is, the boundary of the pigmented and

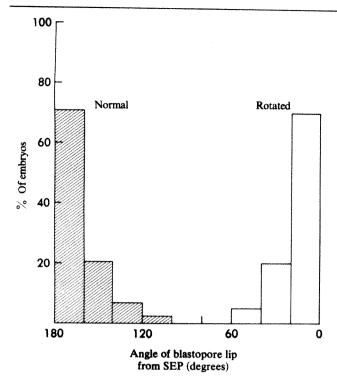

Fig. 1 The topographical relationship of the sperm entry point (SEP) to the dorsal blastopore lip in X. laevis embyros developing from normal and rotated eggs. Unfertilized eggs were squeezed from frogs into 100% MR (100 mM NaCl, 2 mM KCl, 2mM CaCl₂, 1 mM MgCl₂, 5 mM Na-HEPES, pH 7.6) and fertilized in vitro in 30% MR. After fertilization, eggs were dejellied with 2% cysteine hydrochloride, brought to pH 7.9 with NaOH, and washed extensively with 20% MR before storage until use. Procedures were as described elsewhere 28.29. Eggs were placed in 5% Ficoll-20% MR and were marked at the equatorial margin (pigmentation boundary) beneath the SEP by application of a small crystal of Nile red, a sparingly soluble form of Nile blue 16, or by injection of 1% Nile blue in 20 mM sodium phosphate or by injection of 1% Nile blue in 20 mM sodium phosphate, pH 7.4. The rotated eggs were inclined 90° to the side, with the SEP and dye mark uppermost, starting 50 min after fertilization (0.55 on a normalized scale, 19 °C), and continuing for 30 min, at which time the eggs and unrotated controls were transferred to 20% MR where the perivitelline space rehydrated and the eggs returned to gravitational alignment. After 9-15 h, when the blastopore lip first appeared, eggs were scored for the position of the lip relative to the dye mark, by inverting the egg and measuring the angle separating the lip and mark. The histogram places eggs in 20° angular spreads. Normal eggs, not rotated, cluster at the 180° angular separation, that is, the blastopore tends to be opposite the side of sperm entry. Rotated eggs group around a 0° separation, with the lip appearing on the same side as the SEP.

non-pigmented hemispheres) closest to the SEP and have recorded the position of the earliest blastopore lip 10 h later, at the gastrula stage. As shown in Fig. 1, in 70% of eggs, blastopores originate in the sector 160–180° from the dye mark (and hence the SEP of the egg), 27% in the sector 120–160° from the SEP, and 3% in the 100–120° sector. Thus, the SEP is a good but not perfect indicator of the blastopore position and the future dorsal-ventral axis of the embryo.

Dissociation of the topographical relations by gravity

We have repeated and extended with X. laevis eggs several of the experiments of Ancel and Vintemberger¹⁵ who demonstrated the strong control exerted by gravity on axis determination in eggs of Rana fusca. In our modification¹⁶ of their procedure, we have marked dejellied eggs with Nile blue at the equator near the SEP and immersed them in a solution of 5% Ficoll (Pharmacia), a hydrophilic sucrose polymer which dehydrates the perivitelline space and causes the fertilization envelope to collapse on to the egg surface. The egg can then be rotated 90° so that its animal-vegetal axis, which is normally vertical due to the dense yolk of the vegetal hemisphere, is then horizontal. In the Ficoll solution, the rotated egg is unable to return to the vertical orientation in the absence of lubrication from the perivitelline space. Inside the egg, the dense contents of

the vegetal hemisphere flow slowly downwards, driven by gravity, displacing upwards the less dense cytoplasm of the animal hemisphere^{1,15}. These rearrangements continue until the egg is returned to the vertical orientation manually or by transferring the egg to a solution without Ficoll, in which the perivitelline space rehydrates. With reference to the egg's original animal-vegetal axis, gravity causes a slight displacement of cytoplasmic contents towards one side of the egg.

The effect of brief horizontal orientation on axis determination is very striking. Shortly after fertilization, we turned eggs horizontally to a position with the SEP and blue mark uppermost, left them in this orientation at 20 °C for 30 min and then allowed the eggs to develop in the normal orientation until the gastrula stage, when we scored for the position of the earliest blastopore. To our surprise, the blastopore originated directly beneath the blue mark, that is, on the same side of the egg where the sperm had entered. Brief rotation had completely reversed the egg's selection of a dorsal-ventral axis. These data are shown in Fig. 1 on the right side of the histogram: in 70% of eggs the blastopore initiated in the sector 0-20° from the mark, 20% in the 20-40° sector and 10% in 40-60° sector. From observations of the Nile blue mark in the neurula and tailbud stages, we confirmed that dorsal embryonic structures did indeed form from the SEP side of these eggs. We also rotated eggs to horizontal inclinations in which the SEP and dye mark were to the left or right side rather than uppermost, and found that whatever region of the egg equator is uppermost during the rotation period becomes the site of dorsal development in the embryo. Clearly, the egg has selected its dorsal-ventral axis based on its relationship to the gravitational field and not on the position of the SEP. Normally the egg, in its vertical orientation. is free to rotate in the perivitelline space, protected from such gravity-induced lateral rearrangements of its contents.

Figure 2 shows the effects of gravity on eggs at various times from fertilization to first cleavage, as seen using the Ficoll method. Control eggs are shown in the right-hand part of the graph; unrotated eggs gave blastopores approximately opposite (158°) the SEP, and eggs rotated horizontally with the SEP directed downwards gave a narrower angular distribution (173°) than the unrotated controls, as if rotation in that direction reinforces the normal sperm-directed selection of an axis.

In contrast to the controls, the experimental eggs gave clear evidence of axis reversal. As the extent of reversal depends on the time at which the rotation began, the experimental results can be considered in two parts: that is, the effects of gravity in the pre-grey crescent period (time 0.0-0.5) and in the post-grey crescent period (0.5-1.0), where the scale of 0 to 1.0 represents normalized time from fertilization to first cleavage (100 min at 18 °C). The egg is very sensitive to horizontal orientation in the pre-crescent period and reversal is essentially complete. A 12-min period at 90° inclination is sufficient to reverse 100% of the eggs, and an angle of inclination of just 30°, rather than 90°, is fully effective (data not shown). Thus, the normal topographical relation of the SEP to the locus of prospective dorsal development in the egg can be easily disrupted in the precrescent period, with the egg using the gravitational perturbation for its selection of an axis, as was recognized by Ancel and Vintemberger¹⁵

In the post-crescent period, the egg becomes more refractory to the effects of gravity. As shown in Fig. 2, a horizontal inclination starting after the time 0.5 is still effective in determining the axis, although the resistance of the egg to gravity increases between time 0.7 and 0.9 and is essentially complete by 1.0, when first cleavage begins. Pasteels¹ interpreted this resistance as a reflection of the establishment of the grey crescent which, as a cortical determinant, was by definition not perturbable by gravity. Our data do not really fit this interpretation because even at times 0.7 and 0.8, when the grey crescent is fully visible in X. laevis eggs, a significant fraction of the eggs are still affected by gravity. On the other hand, we do not know when grey crescent formation is complete in X. laevis eggs, and note that in other frog species the formation continues

Table 1 Effects of gravity and centrifugal force in the period after grey crescent formation and before first cleavage

Starting time (normalized)	Duration (min)	Force (g)	Angle of inclination of egg, SEP side uppermost	No. of eggs	Position of neural groove (average angle, in degrees from SEP)
(1) —		1	0	470	138
(2) 0.40	20	1	90	109	27
(3) 0.90	20	ī	90	98	140
(4) 0.90	90	i	90	32	141
(5) 0.90	4	26	90	120	112
(6) 0.90	4+90	26 + 1	90	43	74
(7) 0.95	4	50	45	10	30
(8) 0.95	4	50	90	24	20

Eggs of X. laevis were fertilized, dejellied and embedded upright in 9% gelatin (175 Bloom, Sigma)/30% modified Ringer's solution^{28,29} in 35-mm plastic tissue culture dishes. The sperm entry side of each egg was oriented towards a marked side of the dish. The time of the start of gravitational treatment was normalized to the interval from fertilization (0.0) to first cleavage (1.0) and expressed as a fraction of this interval. The treatments were done at room temperature (from 19 to 24 °C) with cleavage times of 100 to 70 min, respectively. In the case of 2, 3 and 4, eggs in gelatin were inclined 90° with the sperm entry side uppermost, at 1 g, by turning the dish on its side. For 5, 7, and 8, eggs in gelatin were centrifuged with the sperm entry side towards the centre of the rotor, that is, uppermost in the centrifugal field. In 6, eggs were centrifuged in this orientation for 4 min and then the dishes were kept inclined at 90° for 90 min with the sperm entry side uppermost. After the gravitational treatment, the eggs were returned to the upright position and incubated at 15 °C for development. After 48 h the embryos were scored for the position of the neural groove and neural folds. The position of the neural groove is recorded as the angle between two vectors originating at the vegetal pole, one passing along the neural groove and one passing through the sperm entry point. An angle of 180° indicates that the neural groove is opposite the side of sperm entry; an angle of 0° indicates that the groove is on the same side.

from 0.5 to 0.8 (refs 17-19). Therefore, we needed to test whether forces >1g could shift the dorsal-ventral axis at still later times.

We used centrifugation to achieve more rapid and extensive movement of the egg contents in the refractory period. Eggs were first embedded and oriented uniformly in a dish of molten gelatin, which, like Ficoll, dehydrates the perivitelline space, and on solidification also holds the eggs in a fixed position. The dish was placed in the centrifuge with the SEP side of the eggs towards the centre of the rotor, so that the centrifugal force would move materials away from it. This orientation is equivalent to that of an egg turned SEP upwards in the gravitational field. After centrifugation, the embedded eggs were incubated in the normal orientation and later scored for the position of definitive dorsal structures, that is, the neural groove and folds, relative to the position of the original SEP. Data are summarized in Table 1. Uncentrifuged control embryos, left in gelatin in the normal vertical orientation, formed the dorsal side at a position averaging 138° from the SEP, a value slightly lower than the 158° found for the blastopore lip position in controls of Fig. 2, perhaps due to limited movement of the gelatin-embedded embryos after gastrulation. As a further control, embedded eggs were turned through 90° at 1g for 20 min starting at 0.4—these developed dorsal structures at a position 20° from the SEP, again indicating the strong effect of gravity on pre-grey crescent eggs. By the time 0.9, eggs turned horizontally at 1g for 20 min, or even for 90 min, in gelatin were completely refractory to gravity.

However, if eggs were centrifuged at 26g for 4 min at 0.9, while oriented with the SEP side uppermost in the centrifugal field, there was a detectable effect on the prospective axis; the dorsal side of the embryo developed, on average, 112° from the SEP. If the 4-min centrifugation at 26g was followed by a 90-min period of horizontal inclination at 1g, the effect was greater, moving the dorsal side to within 74° of the SEP. Finally, if eggs at 0.95 were centrifuged at 50g for 4 min, the dorsal-ventral axis of the embryo was essentially reversed, the dorsal side of the embryo developing within 20° or 30° from the SEP side. The latter treatment was effective until first cleavage, when the developing furrow weakened the egg so that it did not survive the centrifugation. Thus, while the post-crescent period

is characterized by an increasing resistance to gravity, the prospective axis can still be shifted as completely as in the precrescent period, provided more force is applied. Thus, the locus for dorsal development can be completely dissociated from its normal topographical relationship to the grey crescent, well after the time of crescent formation.

Double axis formation

The importance of the grey crescent in dorsalization has been most directly demonstrated by the production of double-axis embryos from eggs grafted with pieces of grey crescent cortex8 However, our data contradict such a role for the grey crescent. It seemed unlikely that the different results could be reconciled by describing the grey crescent cortex as active on transplantation while at the same time easily rearranged or replaced in the egg when exposed to gravitational force. Alternatively, we must ask whether the transplantation results could in some way be an artefact of gravity and not an effect of cortical transplantation. While exploring the effect of increasing centrifugal force on axis position, we found that double-axis embryos can indeed arise at high frequency within a narrow range of conditions of centrifugation. As shown in Table 2 (groups 1 and 3), at a force of 30g applied for 4 min in the period 0.5-0.7, 60-70% of the eggs developed into neurulae with double, opposite, partial or complete sets of dorsal structures, essentially as Siamese twins. Double axes form only if the egg is centrifuged with the SEP side oriented towards the centre of the rotor, that is, in the position uppermost in the centrifugal field. As shown in Table 2 (group 2), when the SEP is directed away from the centre, no twins are formed, and the single dorsal side is centripetal, where the crescent had resided. In this orientation, gravity presumably just

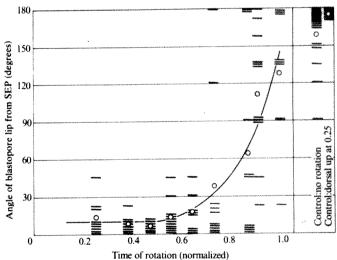

Fig. 2 Position of the dorsal blastopore lip in embryos from X. laevis eggs rotated at various times after fertilization. Eggs were fertilized and dejellied as described in Fig. 1 legend and placed in 20% MR containing 5% Ficoll. The eggs were marked at the prospective ventral equator, that is, on the side of the SEP as described in Fig. 1 legend, and were then left in a vertical position with the animal pole upwards; until the time of rotation when they were turned (90° rotation with SEP uppermost). Eggs remained in the rotated position for 60 min and were then returned to a vertical orientation and allowed to develop in 20% MR. The position of the first appearance of the blastopore lip, ~9-15 h after fertilization (16-21 °C), was scored as the angle between the lip and the dye mark, as described in Fig. 1 legend; 0 indicates superposition of the dye mark and lip, whereas an angle of separation of 180° indicates opposition of the mark and lip. The angle of separation is given on the ordinate, and the time at which the egg was rotated is shown on the abscissa. The time is normalized, with fertilization set as 0.0 and the start of first cleavage set at 1.0. This period ranges from 70 to 130 min depending on the temperature. Data for individual eggs at each time are given as horizontal dashes, while the average for that time is given as an open circle. Control results are shown at the right hand side of the figure: eggs were either left without rotation, or were turned with the dye mark (SEP side) downwards. Note that the latter controls gave an even sharper population response than unrotated controls, for the average angle of separation of the lip and mark. Note also in the experimental series the heterogeneity of the response in the time range 0.7-0.9, when some eggs were affected totally by gravity, a few were not affected at all, and others gave intermediate angles of separation.

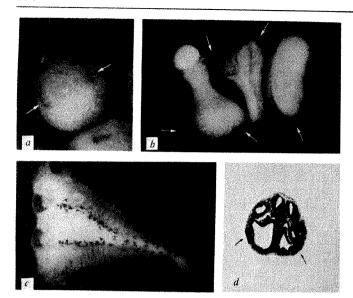

Fig. 3 Twin embryos produced from eggs removed from the fertilization envelope and turned ventral side uppermost, before first cleavage. a, Early gastrula with two blastopores, indicated by arrows; b, three late neurulae, two with double neural grooves and one a control embryo with a single neural groove. The anterior end of each groove is indicated by an arrow. c, Siamese twin at hatching, at about stage 38. One of the axes carries a less well developed head, lacking eyes, although the sucker is present and the trunk is complete. d, Section of a twin embryo, at the posterior head level. Two neural tubes are visible at the top, close together, and two mouth cavities are present at the bottom. Arrows indicate two suckers. The axes were more separated in the mid-trunk region. Paraffin sections were 7 μm thick and were stained with nuclear fast red-aniline blue-orange G.

reinforces the effects of the SEP and the grey crescent on axis determination. Furthermore, even in the orientation favourable for twinning, the extent of rearrangement is critical: at still higher centrifugal force, twins do not form and the single axis forms on the SEP side, that is, that controlled by centrifugal force. This is shown in Table 2, group 4; eggs were centrifuged with the SEP towards the centre of the rotor, as is suitable for twinning, but were subsequently inclined horizontally with the side of the SEP uppermost, to continue lateral displacements of the egg contents at 1g for 90 min. In this case, no twins were formed and the single axis derived from the SEP side, not the side of the grey crescent. Thus, twins seem to develop when the gravitational force is strong enough to create a new dorsal localization in the egg but not so strong as to eliminate the old (SEP-grey crescent-directed) one.

Reservations about cortical grafting results

As high centrifugal force produces double-axis embryos, we attempted to duplicate the conditions at 1g used by Curtis⁸ in his cortical transplantation experiments, to determine whether gravity could also act as a twinning agent there. When the egg was removed from the fertilization envelope by manual dissection and allowed to settle on to an agar surface with its SEP side uppermost, twins were in fact produced. The frequency was quite variable from one egg batch to the next and as shown in Table 2, we found two batches (that is, from two different frogs) giving 50-70% double-axis embryos, three batches giving 30-49%, eight giving 10-29% and eight giving 0-9%. Figure 3a shows an example of a double blastopore of an early gastrula from an egg turned horizontally with the SEP side uppermost starting at 0.8, and left in this orientation until the 16-cell stage. Examples of double neurulae and of a hatching-stage Siamese twin are shown in Fig. 3b and c, respectively. Histological analysis confirmed the presence of doubled internal dorsal structures (Fig. 3d).

With regard to the conditions required for twinning by this procedure, it should first be mentioned that eggs removed from the fertilization envelope lack a perivitelline space and remain in the orientation in which they are put intentionally or by chance.

Therefore, just as in the Ficoll treatment, they cannot return to the vertical orientation and are susceptible to gravity-induced displacements of the egg contents. Second, twinning has been observed by us only in eggs oriented with the SEP side, that is, the prospective ventral side, uppermost. Table 2 records no double-axis embryos for two sets of eggs oriented with the SEP directed downwards, that is, prospective dorsal side uppermost; eggs of these same batches gave 20% and 35% twins when oriented SEP upwards. This requirement is the same as found for twinning by centrifugation and implies the importance of having gravity oppose rather than reinforce the effects of the sperm and grey crescent on axis selection. Third, extreme flattening of the egg which occurs on its removal from the fertilization envelope may also be an important precondition for twinning at 1g, thereby explaining why we rarely observed twins (never more than 5%) in our experiments when eggs were rotated SEP side uppermost in Ficoll or gelatin, as these eggs largely retain their spherical shape. Thus, with the proper choice of conditions, gravity can cause the formation of double-axis embryos in \bar{X} . laevis. Double blastopores and secondary embryonic axes due to gravitational effects have been previously reported by Pasteels¹ using an axolotl egg turned with the prospective ventral side directed upwards shortly after grey crescent formation, by Kubota²⁰ with Rana nigromaculata eggs inclined horizontally at the time of crescent formation, and by Schultze²¹, Penners and Schleip²² and Penners²³ with inverted and flattened R. fusca eggs.

Because of these results, we question Curtis' interpretation⁸ that double-axis embryos in his experiments owe their origin to the implantation of grey crescent cortex. To implant the graft, Curtis had to remove the fertilization envelope of the recipient egg, which means that the egg was no longer free to control its

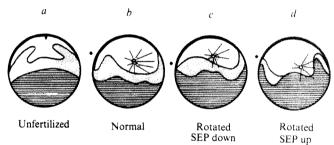

Fig. 4 Dorsal-ventral rearrangements of the cytoplasmic contents of X. laevis eggs. Eggs were fixed at various times in Bouin d'Hollande fixative, dehydrated, embedded in paraffin, sectioned at 6 µm along the prospective dorsal-ventral axis and stained with azofuchsin-aniline blue-orange G. Median sections along the prospective dorsal-ventral axis were examined for regional differences in the size and number of yolk platelets, the presence of pigment granules, aster and spindle fibres, and pronuclei. Schemes of representative sections are shown; this was necessary as only the highestquality colour reproductions preserve the regional differences seen under the microscope. Photographs of actual sections will be presented elsewhere 14. In the drawings, the region of large, closely packed vegetal platelets is indicated by cross-hatching; the intermediate size, closely packed equatorial platelets are indicated by dots, and the animal hemisphere region of small dispersed platelets and abundant cytoplasm is indicated by an open area. In all cases the egg is oriented animal hemisphere uppermost, and in the case of fertilized eggs, the SEP is at the left side of the egg, at or slightly above the equatorial level, as indicated by the asterisk. a, Drawing of an unfertilized egg, showing the radial distribution of contents. At the animal pole of the egg is the second meiotic spindle. b, A fertilized egg fixed at 0.6, well after the grey crescent became visible. The egg has been kept in the normal vertical orientation. Note the upward trail of intermediate and large yolk platelets on the prospective dorsal side of the egg. The region of the grey crescent is indicated by the raised boundary of pigment granules in the cortex. Dorsal structures will arise from this region of the egg, that is, opposite the SEP side. The sperm aster with paired pronuclei is still clearly visible. c, An egg turned horizontally with the SEP down from 0.26-0.5, fixed at 0.6. Note the trail of large and intermediate yolk on the right-hand side, occupying about the same position as in a normal (non-rotated) egg. This egg, like a non-rotated egg, would develop dorsal structures from the right side, the side opposite the SEP (asterisk). d, An egg which was turned horizontally with the SEP side upwards, starting at 0.28 and remaining until 0.5. It was subsequently fixed at 0.7. Note the trail of yolk at the left-hand side of the egg, the SEP side (asterisk). The horizontal orientation allowed gravity to displace cytoplasmic contents away from the SEP side, leaving the trail of yolk behind. The dorsal structures of the embryo will arise from the SEP side of this egg, instead of opposite the SEP.

Table 2 Secondary axis formation (twinning) by X lacous oggs perturbed by centrifugal force or gravity

•	-

(9) 0.5–1.0	Until 16-cell stage	1	45-90°, SEP down	34 (2 frogs)	0

Eggs were fertilized, described, and either embedded in 9% gelatin/30% modified Rmger's solution (MR)^{26,26} with the SEP towards the marked side of the dish or immersed in 6% Flooli-20% MR²⁶. The gelatin-embedded eggs (rows 1-4) were centrifuged as described in Table 1 legend at 700 r.p.m. (30g) for 4 mln, starting at 0.60 or 0.65 as indicated. During contribugation, the eggs of rows 1, 3 and 4 were oriented with the SEP side towards (SEP in) the centre of the rotor whereas the eggs of row 2 had the SEP sade away (SEP out) from the rotor centre. These orientations correspond to having the animal-vegetal axis of the egg horizontal (90°) in the centralugal field with the SEP side up or down, respectively. In the case of Ficoll-treated eggs (rows 5-9), the fertilization envelopes were removed manually using forceps, and starting in the time period 0.5-1.0 the eggs were turned SEP side uppermost (rows 5, 6, 7 and 8) or down (row 9) on an agar surface in 20% MR containing 50 µg mi⁻¹ gentamycin. Eggs were kept in this orientation until the 16- or 32-cell stage and then were transferred to hemspheric wells in agar in 20% MR-gentamycin to enhance advanced development of the embryos. The treatments were done at room temperature (19-23 °C). The number and completeness of the axes were scored at stages from late neurula to advanced tailbud when suckers were identifiable.

orientation. As shown in ref. 8, Fig. A, B, his recipient eggs were inclined 45°-90° to the side in the period of grafting or recovery, which is the orientation required for gravity to cause lateral displacements of the egg contents. We assume that eggs receiving grafts in the ventral margin were turned slightly with this side uppermost, to receive the graft; this would be the condition for twinning by gravity. Implantations in this position are the ones for which Curtis observed double-axis embryos and which led him to conclude the dorsalizing activity of the graft. The critical control for these experimental manipulations would have been a grafting of a piece of non-grey crescent cortex (for example, ventral margin cortex) into the ventral side of a recipient egg. If the source of the cortex is critical, such recipients should develop only a single axis; if unrecognized gravitational effects are responsible, the recipients should still twin. Although Curtis did not report this control, he did use several others involving grafts of grey crescent, animal pole and ventral cortex, but all were implanted in the dorsal (that is, grey crescent) side of the egg. If these eggs were turned slightly with dorsal side uppermost to receive the graft, they would not be expected to give twins, according to our results, as, in this orientation, gravity would only reinforce the normal sperm and grey crescent-dependent dorsalization of the egg. In fact, in Curtis' experiments, all implantations to the dorsal margin gave single-axis embryos. We suggest that these were not appropriate controls for the ventral implantations, all of which gave twins.

Although we cannot prove that Curtis' grafts of grey crescent cortex did not have transplantable dorsalizing activity, we question such an interpretation since we can obtain twinning without cortical transplantation, simply by exposing eggs to experimental conditions close to, if not identical, to those used by him. It seems plausible to us that the critical agent was not the cortical graft but gravity acting on an egg that was turned ventral side uppermost.

The role of the grey crescent

We suggest that the grey crescent is a manifestation of an early dorsalizing process but is not itself a transplantable dorsal determinant or source of a lasting cortical field. Although the mechanism of grey crescent formation is unknown, and may differ among various amphibia24, Lovtrup25 and Palacek et al.1 suggest that in X. laevis the crescent develops opposite the sperm entry side because a large asymmetric contraction of the egg cortex draws pigment granules of the animal hemisphere towards the sperm entry side, leaving a visibly depigmented crescent on the dorsal side. We suggest that this asymmetric contraction as a whole is an early dorsalizing mechanism important for establishing regional cytoplasmic differences along the prospective dorsal-ventral axis of the egg. The target of the contraction would not be the cortex, but deeper, movable cytoplasmic materials. Pasteels1 observed in sections of postgrey crescent eggs of R. fusca a trail of displaced vegetal yolk associated with the cortex on the dorsal side and suggested that it was pulled upwards during grey crescent formation. Klag and Ubbels²⁶ observed similar dorsal displacements in eggs of Discoglossus pictus.

Figure 4a, b shows schematic diagrams of actual sections of X. laevis eggs, in one case before fertilization when the egg contents are arranged with radial symmetry and in the other case at 0.6 when the egg has already acquired a detectable asymmetry along its dorsal-ventral axis. The displacement of yolk is discernible on the prospective dorsal side, while the ventral side has a quite different distribution of materials. Actin filaments of the cortex presumably participate in the contraction, but microtubules must also play a part since inhibitors such as colchicine and vinblastine block grey crescent formation and cytoplasmic displacements 14,18. We propose that a vectorial contraction of the cortex normally induces a rearrangement of the egg's cytoplasmic contents, forming a cytoplasmic localization necessary for the eventual induction of dorsal mesoderm.

Although in X. laevis the cortical contraction probably operates only in the time period 0.5-0.8, gravity may be able to generate a comparable dorsal-ventral asymmetry at earlier or later times, perhaps until the egg cytoskeleton or cleavage furrows interfere. Figure 4c shows a schematic section of an X. laevis egg rotated horizontally with SEP directed downwards, an orientation in which gravity reinforces normal axis formation. The cytoplasmic distribution of this egg is equivalent to that of the normal egg shown in Fig. 4b; in Fig. 4d a similar egg has been turned horizontally with the SEP uppermost, an orientation leading to axis reversal. In this case the trail of vegetal volk appears on the same side as the SEP, roughly the mirror image of the normal egg in Fig. 4b. Thus, the cytoplasmic distributions correlate with axis reversal. We have not yet sectioned eggs obtained in conditions which favour twinning, but we might expect double symmetrical trails of yolk. Cytological studies of normal, rotated and centrifuged eggs will be presented in detail elsewhere14.

Initially the sperm must in some way determine the position of the prospective dorsal-ventral axis of the egg, because the grey crescent, blastopore, and dorsal structures normally arise on the side opposite its random point of entry. Since the cortex contracts towards the side of sperm entry, the question becomes one of how the sperm orients this contraction. Soon after entering the egg, the sperm produces a large aster, organized presumably by its centriole 18,27. The astral microtubules cause a slight redistribution of cytoplasmic contents along the future dorsal-ventral axis. The antimicrotubule drugs colchicine and vinblastine block aster assembly and in their presence the cytoplasmic displacements do not occur¹⁴. Similarly, artificially activated eggs of X. laevis, lacking a functional centriole, do not have these early displacements. We suggest that this initial slight aster-driven asymmetry cues the direction of the cortical contraction, that in turn leads to the major cytoplasmic.

redistribution shown in Fig. 4b. It seems consistent that the X. laevis egg is more sensitive to the axis-orienting effects of gravity in the pre-crescent period than in the post-crescent period, since at early stages, gravity, like the sperm aster, needs only to create a small lateral displacement of cytoplasmic materials to cue the cortical contraction. In the post-grey crescent period, larger forces, afforded by centrifugation, are required to reverse the cytoplasmic distribution accomplished by the contraction and to create a new and opposite one

In summary, the important dorsal-ventral regional differences arising in the fertilized egg before first cleavage appear to reside not in the grey crescent cortex but in cytoplasmic materials reorganized normally by the sperm aster and cortical contraction, or experimentally by gravitational force.

While the cortex, including the grey crescent, would be part of the cellular machinery used by the egg to generate a dorsal cytoplasmic localization, it would not itself be a lasting repository of developmental information. We do not know which important materials undergo redistribution on the dorsal side of the egg, nor is it known how these materials serve in the formation of the inductively active vegetal cells of the midblastula.

We thank Professor Pieter Nieuwkoop for allowing M.K and J.G. the opportunity to visit and work at the Hubrecht Laboratory at the start of this study. This research was supported by USPHS grants GM 19363 (to J.G.) and GM 26875 (to M.K.), by American Cancer Society grant CD 113 (to M.K.), and by the Royal Netherlands Academy of Arts and Sciences. Estimates of total quantity of meteorites in the East Antarctic ice cap

Edward J. Olsen

Field Museum of Natural History, Chicago, Illinois 60605, USA

Since 1969 ~5,000 meteorite fragments have been recovered from two regions, the Yamato Mountains and Victorialand, on opposite sides of the East Antarctic ice cap^{1,2}. Based on a steady-state model for the ice cap3, and current estimates of meteorite influx4, a model is developed here which predicts that the steady-state number of meteorites being carried in and on the ice is at least 760,000. Most of these are being carried within the ice and are only exposed at peripheral regions by a combination of wind ablation and blockage of ice movement by protruding mountain barriers. The large steady-state population of meteorites does not require unusual conditions of influx. It is solely the cold, dry climate which preserves virtually all meteorites that fall except for the fragile, porous carbonaceous chondrites. The same model applied to the Greenland ice cap indicates a steady-state population of ~61,000 meteorites.

The East Antarctic ice cap has several properties that permit some simplifications in developing a model for it, without loss of generality. The area is roughly elliptical with major and minor diameters of ~4,000 km and 3,000 km, respectively. It has an area of $9.4 \times 10^6 \, \mathrm{km^2}$ and a single major centre of ice flow. The calculated circumference is 1.11×10^4 km. For the purpose of this model, the calculation is simplified if an equivalent circle is used with the same area and almost identical circumference. The equivalent circular continent would have a radius of 1,730 km (area $9.4 \times 10^6 \text{ km}^2$, circumference = $1.09 \times 10^4 \text{ km}$).

Meteorites falling randomly over the ice cap are carried in and on the ice radially coastwards. Initially, we consider that there is no blockage of movement and each meteorite reaches the coast where it is lost by calving of the ice into the sea. After some time a steady-state population, Q, of meteorites will be reached in the ice cap. A simple relationship can be derived, Q = sF/2v, where F is the influx rate (meteorites yr^{-1} for the total area, $9.4 \times$ 10^6 km^2), s is the distance travelled (m), and v is the mean velocity of travel (m yr⁻¹). The time for the steady state to be established is T(yr) = s/v. Based on a steady-state ice cap profile, as well as actual measurements in the field, the velocity near the coast is higher than in the interior.

Nagata² has developed a model for the longitudinal profile of a steady-state ice cap. In it he derives analytical expressions relating v to s and a parameter, b, the accumulation rate of ice expressed in m yr⁻¹ of water equivalent.

To determine how v varies with distance from the centre to the edge some estimates of b are needed. For East Antarctica Paterson⁵ states that accumulation ranges from $b = 0.03 \text{ m yr}^{-1}$ in the central part to $\sim 0.60 \text{ m yr}^{-1}$ near the coast. Measured velocities range from $\leq 1 \text{ m yr}^{-1}$ in the central part to over 300 m yr⁻¹ near the coast^{5,6}. These observations were used in conjunction with the Nagata model to model the velocity from the centre to the coast. A tabulation of velocities was prepared but no attempt was made to fit them by an analytical expression.

Hughes⁴ has summarized data on meteorite influx rates. The value of F to be used in the calculation of Q depends on the mass of the smallest meteorite to be considered. If dust grains are considered then Q would be very large; if ton-size meteorites are considered then Q would be very small. In Antarctica. within an area of concentration, specimens as small as 0.1-0.87 g have been collected^{7,8}. These, however, are clearly fragments from larger masses that have suffered extensive fragmentation. Thus, an estimate of the fragmentation factor is needed.

Based on the proportion of irons and pallasites to stone meteorites in the Yamato recovery region, relative to worldwide observed falls, Nagata² estimates a factor of 3. The same analysis applied to the Victorialand finds gives a value of 5. King et al. have attempted to pair many of the Victorialand specimens

based on field occurrence, macroscopic and microscopic appearances. Their suggested pairings indicate a factor between 3 and 4. Thus, a factor of 4 ± 1 seems to be indicated, which seems remarkably low. Antarctic meteorites suffer four fragmentation processes: (1) normal break-up during atmospheric passage (Hellyer¹⁰ states that about half of observed falls are multiply fragmented); (2) fragmentation on impact on ice; (3) crushing while being carried within the ice during transport; (4) frost-breakage while exposed in concentration areas near the ice periphery (dark rocks are warmed above the freezing point of water during summer months, allowing moisture within them to melt and then refreeze during the dark winter months). A better method to determine fragmentation would be to compare the distribution of recovered masses with the masses of observed meteorite falls. The data on the recoveries in Victorialand through 1979 have been tabulated by Score et al.". The distribution of masses is highly skewed. The mean mass is 1,910 g. while the median is 235 g and the mode is 15 g. Hughes¹¹ has plotted the distribution of recovered masses among 755 observed falls. The histogram shows a mode at 3 kg. If we assume that the mode of observed falls is a good measure of the highest frequency of meteorite masses that survive entry, then comparison of the mode of the Victorialand finds, 15 g, with this 3 kg figure indicates the most frequent fragmentation factor is 200. This seems to be a more reasonable number. Although iron meteorites clearly fragment less readily than stone meteorites, data on observed falls indicate that over 91% are stones. Thus, based on data for observed falls, the most frequent mass surviving entry is 3 kg. In Antarctica the most frequent size of fragment is 15 g. A 15-g meteorite is readily observed on the ice in Antarctic field conditions.

Hughes4 has fitted an equation to the observed data on recovered masses (non-Antarctic) for the mass range ≥16 kg. Extrapolation of this equation to 3 kg gives a worldwide influx rate of 3,500 meteorites yr⁻¹. This number is in good agreement with an estimate of 3,300 based on Hughes' analysis of data presented by Brown¹² and tabulated in ref. 4. Both Halliday and Hughes (personal communications) agree this is the most reasonable figure to use based on current data. In addition, Halliday¹³ has determined a latitude effect by analysis of meteorite orbits. This effect depends on the initial velocity of a meteorite encountering the Earth. Those with a velocity of 15 km s⁻¹ will be $\sim 20\%$ less frequent at high latitudes (70°-90°, N or S) relative to equatorial latitudes; those with a velocity of 25 km s⁻¹ will be 40-50% less frequent at high latitudes. ReVelle¹⁴ has developed a model for the mass-loss (ablation) of chondrites falling through the Earth's atmosphere. From it one can conclude that most meteorites that survive entry are the slower ones4. Thus, for Antarctica a reduction of 20% will be used for the latitude effect. The value of F for East Antarctica is then 48.6 meteorites of 3 kg mass or larger per year.

Tabulated mean values of v were used in each of 10 concentric subregions, of equal area, from the centre to the edge of the continent, and the respective values of Q were determined and summed. The steady-state quantity of meteorites is $Q = 529,000 \ (1.06 \times 10^8 \ \text{fragments})$. The time required for the steady state to be established is $22,000 \ \text{yr}$, which is short compared with the age of the ice cap¹⁵. In these computations it was assumed that effects due to ice surging movement average out over this time span.

These computations assume that no blockage or retardation of ice occurs. In reality $\sim 47\%$ of the East Antarctic perimeter consists of protruding mountains that cause significant retardation of ice movement. In the vicinity of the Yamato Mountains horizontal velocities of 1 to 0.5 m yr⁻¹ have been measured². Assuming 1 m yr⁻¹ in the vicinities of these barriers, and 47% of the perimeter affected, the effect is to increase the value of Q to 760,000 meteorites $(1.5 \times 10^4 \text{ fragments})$.

The computations, so far, have assumed that each meteorite lands on the ice and is carried, either in it or on it, in a straight line path to the perimeter. Clearly, this cannot be the case as ice-buried topographic highs, subsidiary flow centres on the ice

(such as the Fuji Divide near, and upstream from the Yamato Mountains), and local variations in accumulation rate cause the ice to move along on less-than-direct lines. For any path that meanders from the direct path the effect is to increase the value of Q. There is no way, quantitatively, to assess the magnitude of this effect over the whole ice cap. Thus, the value of Q determined above is a minimum.

Finally, one additional process can affect the value of Q. It has been assumed so far that v is not a function of depth within the ice at which a meteorite is carried. Clearly, as accumulation takes place over time, any meteorite that fell in an earlier time will be buried as it is carried along. Variation of velocity with depth is not believed to be a large factor. Velocity is considered almost constant from the ice surface down to about half of full depth. What happens below half depth, especially near the bottom, is not thoroughly understood and several possibilities exist. In terms of Nagata's model this factor does not seem to affect Q significantly.

Considering all the assumptions and simplifications in the foregoing model it can be concluded that the East Antarctic ice cap contains, at any given time, the order of 760,000 individual meteorites, in the mass range >3 kg, and comprising $\sim 1.5 \times 10^8$ fragments. If these numbers are applied to the Yamato Mountains, and if the velocity near the Yamato barrier (~ 40 km wide) is taken to be 1 m yr⁻¹, the ice field in front of the mountains would have a steady-state population of about 3,000 individual meteorites. This does not take into consideration the lateral convergence effect described by Nagata², which would increase this number. Even at that, this estimate is of the order of magnitude estimated by Yanai¹⁸ of < 8,000 for this region.

The mechanism by which unusual concentration fields occur, as proposed by Nagata², has permitted large numbers of meteorite fragments to be recovered within relatively small areas. On the other hand, the work of Cassidy and colleagues in southern Victorial and 1,19 shows that concentration fields are not the only way Antarctic meteorites will be recovered. Several meteorites have been encountered that were clearly moving along alone. A prime example of this is the Mt Baldr meteorite (two main fragments with missing fragments) that was found on the surface of a segment of ice cap within a few kilometres of, and moving towards, a major ice-fall onto Wright Upper Glacier at the head of one of the Dry Valleys; no barrier was present. While lateral concentration helps in recovering large numbers of specimens, the key factor in Antarcrica is the low rate of weathering at low temperatures, which preserves most of the meteorites that land on the ice cap. This is borne out by the terrestrial ages of Antarctic meteorites which are, on the average, significantly older than finds from lower latitudes²⁰ Because of the general condition of ablation by wind in peripheral regions of the ice cap (an integral part of the Nagata steady-state profile model³) meteorites carried within the ice have a high probability of being exposed in these regions. This means that bare blue ice, free from snow cover in peripheral regions, can yield meteorites with or without lateral concentration. Thus far, all meteorites found in East Antarctica, including the first finds in earlier decades of this century, have been recovered from peripheral regions.

Antarctica, however, cannot be considered a place where every meteorite is preserved. Because of the great detail in which Japanese field teams have studied the Yamato Mountains concentration area, data on the distribution of meteorite types there are quite good. Note that carbonaceous chondrites are under-represented, relative to worldwide recovery ratios, by a factor of three². This indicates that their low mechanical strength, plus their high porosity causes them to be preferentially destroyed by a combination of crushing and weathering when carried within the ice.

If this model is applied to the Greenland ice cap (without consideration of any coastal barriers) it suggests that \sim 61,000 meteorites (1.2×10⁷ fragments) are in steady-state residence. Unfortunately, most of the Greenland ice cap is snow covered. Meteorological conditions are different from those in Antarctica

because of its subpolar position. Only a couple of relatively snow-free regions in north-east Greenland seem suitable for potential meteorite recoveries.

I thank Professor Charles Bentley for help in finding some of the glaciological literature, Dr W. A. Cassidy and Dr K. Yanai for stimulating discussion, also Drs Ian Halliday and David Hughes for helpful criticism on the worldwide meteorite influx rate problem. Finally, I benefited from discussion with Ms D. Eatough. This work was supported by the Chalmers Fund of the Field Museum of Natural History and a grant from the NASA.

Among the diverse lattice defects occurring in natural diamonds, none has engendered so much controversy as the 'platelets', those planar defects which lie on {100} planes of the diamond matrix and whose diameters commonly lie in the range 10-100 nm. For many years, the only evidence for the existence of platelets was indirect, residing in the reported anomalous 'spike' diffuse X-ray reflections1, but it was eventually accepted that these diffuse reflections could not be due to thermal vibrations but arose from static lattice disorder2. Guinier3 and Frank4 independently pointed out that the defects responsible for the 'spike' reflections must be plate-like, lying in {100}. Direct proof of the existence of platelets came with the transmission electron microscope (TEM) observations of Evans and Phaal⁵, and it has been shown that the platelet structure is extrinsic, that is, that it forces apart the diamond matrix on either side of the platelet°. We now report a new and more reliable way of measuring the magnitude of matrix displacement produced by platelets.

Moiré techniques are widely used for measuring small displacements of one periodic object relative to another of similar periodicity. If the two periodic objects are crystal plates superposed on each other in nearly parallel orientation and simultaneously diffracting from the same Bragg planes, then relative displacement of the two plates can be measured to a small fraction of a nanometre, whether electrons or X rays are being diffracted⁷⁻⁹. When studying atomic-scale displacements due to lattice defects, interpretation can be straightforward if a defectfree comparison crystal (1) is superimposed on the defectcontaining specimen crystal (2). In the case of dislocations in (2) outcropping at the interface between (1) and (2), the number of moiré fringes terminating at a dislocation outcrop is $\mathbf{g} \cdot \mathbf{b}$, where g is the reciprocal lattice vector of the active Bragg reflection and b is the Burgers vector of the dislocation^{8.9}. Furthermore, if crystal (2) contains a planar defect such as a stacking fault which involves a relative translation, f, between crystal matrices on either side of the defect, and the defect outcrops at the interface between (1) and (2), then the moiré fringe pattern will appear faulted at the defect outcrop, the fringe displacement at the outcrop being g · f fringe periods.

In our TEM studies of platelet defects in diamonds we prepared thin specimens parallel to (110). We then viewed platelets parallel to (001) edge-on and those parallel to (100) and (010) obliquely, when the electron beam is normal to the specimen surface (Fig. 5 of ref. 10 explains this geometry). The specimens are produced by sawing, mechanically polishing and ion-beam thinning. In one such specimen, cracking had occurred on the cleavage planes $(\bar{1}11)$ and $(\bar{1}1\bar{1})$ normal to the specimen plate, and on one of the cleavage planes inclined at 35.25° to its surface. Following cracking, small overthrusts had taken place, producing narrow strips of overlap in which the specimen laminae above and below were slightly rotated with respect to each other. The moiré patterns appearing in the overlap regions were usually complicated due to warping of the overlapping laminae and the mutual proximity of the platelets. However, one strip of overlap in which the moiré pattern can be straightforwardly interpreted is shown in Figs 1 and 2. This region was first observed in the high-resolution JEOL 200CX microscope at Oxford, operating at 200 kV. The set of two-beam diffraction contrast patterns reproduced here were photographed in Bristol with a Philips 400 microscope operating at 120 kV. (The corresponding electron diffraction patterns were also recorded.) The important reflections 004 and 220 were photographed by dark-field (DF) as well as by bright-field (BF) technique. In the area shown, each lamina is ~33 nm thick. The vertically oriented boundaries of the overlap strip are the cleavage planes ($\overline{1}11$). The boundary sloping up towards the right at the top of Figs 1 and 2 is parallel to $(\overline{1}1\overline{1})$. Except where the platelet strain fields influence the pattern, the moiré fringes are almost parallel and equispaced, and they lie parallel to the g vector of the Bragg reflection active. The basic pattern is thus a pure rotation moiré, the rotation measured from it being ~7 mrad.

The field in the Figs 1 and 2 contains nine platelets, four of which lie parallel to (001) and are seen edge-on giving sharp traces rotated 35° clockwise from the horizontal. The platelets in this specimen (as in many other specimens) are elongated along one of the (110) directions in the platelet plane; they tend to be lath-like, with their long pair of edges lying straight and parallel to the $\langle 110 \rangle$ direction of elongation. In a field of $\sim 1 \,\mu\text{m}^2$ surrounding the region exhibited here, roughly half of the \sim 20 platelets lying on (100) and (010) appear to outcrop on both top and bottom surfaces of the lamina containing them. This shows that their lengths parallel to the lath axis exceed 66 nm, twice the lamina thickness, as these lath axes make 60° with [110], the normal to the specimen lamina. Consequently, there is a good chance that platelets on (001) having their long axis parallel to [110] are seen with their two [110]-direction edges running straight from top to bottom of the lamina, when the direction of view of the specimen is close to [110]. The images of their edges look exactly like the images of pure edge dislocations viewed parallel to the dislocation line (as indeed they should). A platelet

[§] Present address: School of Physics, University of Melbourne, Parkville 3052, Victoria,

To whom correspondence should be addressed

image with such properties is exhibited by one of the two (001) platelets partly covered by the overlap—the platelet in the centre of the field. It can be distinctly recognized both within the overlap region (by virtue of the clear-cut displacement of the moiré fringes) and in the single lamina region to the right of the overlap; it is best seen in Fig. 1b. (The lamina on the right thus corresponds to the defect-containing crystal (2), whereas that on the left is the comparison crystal (1).)

The lower platelet in the overlap region does not give a clearly defined displacement to the moiré fringes, the confusion in its fringe pattern being especially noticeable in the higher order reflection 004. We conclude that this platelet either does not outcrop at all at the interface between (1) and (2), or that the outcrop length is small relative to the platelet diameter. The perturbation to the fringe pattern arises because electrons pass through crystal that is locally tilted due to the dislocation-type strain field at the platelet periphery.

The conditions to be satisfied so that lattice displacement can be precisely derived from the moiré fringe displacement at the image of the planar defect are that both the crystal thickness and the crystal orientation are the same on either side of the plane of the defect. The former condition certainly holds in the present

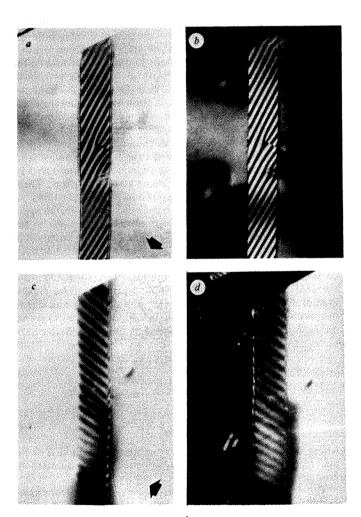

Fig. 1 Bright field and dark field electron micrographs of a platelet-containing Type Ia diamond in which moiré fringes appear where cleavage and overthrust have led to superposition of crystal laminae. The field width is 0.3 μ m, the width of overlap 66 nm. The trace of ($\bar{1}11$) is vertical. The micrograph print orientation reproduces a view of the image as seen on the fluorescent screen of the microscope; the specimen axis [110] points towards the observer, the electron beam direction is [$\bar{1}10$]. Arrowheads indicate the direction of the active g vectors. a, 004 reflection, BF; b, 004 reflection, DF; c, $\bar{2}20$ reflection, BF; d, $\bar{2}20$ reflection, DF.

experiments. The latter condition applies when the platelet outcrop at the interface between crystals (1) and (2) is sufficiently extended, and is satisfied in the case of the upper platelet. In the 004 BF (Fig. 1a) and DF (Fig. 1b) images, a circuit enclosing the left-hand edge of the upper platelet shows the number of extra fringes to be slightly less than 15: our Lest estimate lies between 1.40 and 1.45. Figure 3 shows the way the fringes can be counted. For example, one may take a circuit up the right-hand margin of the overlap from fringes 3' to 1', then down along fringe 1'-1 to the left-hand margin where one proceeds to fringe 3, and then finally up along fringe 3 to the discontinuity at the platelet. The whole extra fringe is designated X; the fraction in excess of unity is assessed from the relative spacings at the platelet between fringes 2 and 3', and 3' and 3. The 220 BF (Fig. 1c) and DF (Fig. 1d) fringe patterns show no detectable fringe faulting due to the platelets.

Although our moiré experiments have only included Bragg reflections from planes containing [110], and are thus insensitive to translations parallel to [110], it is reasonable to take Fig. 1c and d as direct evidence confirming that the matrix displacements produced by the platelet structure are perpendicular to the platelet plane. Taking $\mathbf{g} \cdot \mathbf{f}$ for the 004 reflection to be bracketed between the values 1.40 and 1.45, and \mathbf{f} parallel to [001], gives a bracket for the magnitude of \mathbf{f} between 0.35 a_0 and 0.362 a_0 , a_0 being the face-centred cubic lattice parameter of diamond, 0.357 nm.

Although Fig. 2a and b do not provide very accurate values of the displacement, their fringe shifts are quite consistent with the displacement value obtained from Fig. La and b. Note in Fig. La and b that the fringes are deviated as they approach the middle regions of the platelet. This is predictable from the strain field of the two parallel edge dislocations which are coincident with the platelet edges, and whose Burgers vector equals the platelet displacement. The calculated change in orientation of fringes 2 and 3 relative to the average fringe direction in the overlap region is $\sim 7.5^{\circ}$. Measurement, which can only be approximate, gives between 8° and 9°, in as good agreement as can be expected. The lower part of Fig. 2a shows a second fringe system. The orientation and spacing of these fringes, together with the diffraction pattern photographs, identify them as due to the 224 reflection. The strong excitation of the 224 reflection in this region is probably a consequence of specimen bending due to local contamination. In most of the micrographs one can see fine fringes parallel to the vertical boundaries of the overlap region. These arise partly from defocus, partly from refraction at the cleavage edge and partly from a contamination layer.

What is the nature of platelets? They are known to occur in association with nitrogen impurity in the commonest natural

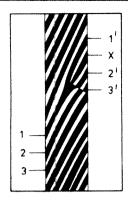

Fig. 3 Diagrammatic representation of the central part of Figs 1 and 2 showing the moiré fringe configuration as seen in Fig. 1a or b, and the numbering of fringes adopted for measuring the fringe displacement at the platelet.

diamonds (designated Type 1a). In these diamonds nitrogen is present in several non-paramagnetic aggregations, each of which has characteristic optical absorption spectra (see ref. 11 for details on optical properties and impurities in diamond). Platelets are absent in the common synthetic and the very rare natural Type 1b diamond in which nitrogen occurs in the singly substituted atomic state. Platelets are also absent in Type II diamonds, which are sufficiently pure to be free of nitrogendependent optical absorptions. The simplest interpretation of evidence from X-ray diffraction 'spikes' is that the lattice displacement due to platelets is close to 1/3 a_0 normal to the platelet plane. However, considerable complications attend the performance and interpretation of the X-ray experiments¹². A platelet structure has been proposed¹³ in which pairs of nitrogen atoms replace single carbon atoms of one of the sub-lattices of the diamond structure and form a single sheet of di-nitrogens parallel to a cube plane, the N-N bonds being perpendicular to the sheet. This model displaces the diamond matrix by about 1/3 a_0 perpendicular to the platelet plane, in accord with the X-ray evidence. Although non-nitrogen-containing platelet structures have been proposed 14,15, a platelet structure is now favoured in which nitrogen is at least an important constituent 16,17. There is scope for platelet-structure model-making, and it is important to have a strictly accurate value for the lattice displacement produced by the platelet structure. As more moiré data become available, it should be possible to narrow the uncertainty in displacement magnitude. As it stands, the present experiment provides the best and most direct measurement obtained to date.

We thank Professor Sir Charles Frank, FRS, and Professor Sir Peter Hirsch, FRS, for their interest in this work. Financial support from the UK SRC and from De Beers Industrial Diamond Division (Pty) Ltd is acknowledged.

Drag reduction in fibre suspension

W. D. McComb & K. T. J. Chan

School of Engineering, University of Edinburgh, Edinburgh EH9 3JL, UK

Spectacular reductions in turbulent friction can be obtained by adding small amounts of either long-chain polymers^{1,2}, or macroscopic fibres3,4 to a fluid. The polymer effect has been the more studied of the two. But one of the continuing puzzles is that measurements of the turbulent energy spectrum show no evidence of a direct eddy-polymer interaction, despite the fact that the influence of the polymers on the turbulence is so profound. Although some increase in energy may be observed at small wavenumbers (attributable to a decrease in the dissipation rate), inertial and dissipation range spectra in polymer solutions are unchanged from the newtonian result. In contrast with this situation, we have recently found very marked changes in energy spectra measured in fibre suspensions.

Although there are many similarities between the effects of the two kinds of additive, they are thought to involve different mechanisms. For example, use of polymers and fibres together can produce much larger reductions in drag than would be the case with either additive on its own⁵. We have previously reported measurements using laser-Doppler anemometry (LDA) which indicate that the turbulent structure in dragreducing fibre suspensions is not the same as that in polymer solutions⁶ (and both, of course, differ from newtonian fluids). Furthermore, as the fibres were degraded by repeated passage through the apparatus, we observed an apparent transition from 'fibre-like' to 'polymer-like' drag reduction, as measured by mean and r.m.s. velocity distributions across the pipe⁶. These remarks apply only to typical drag-reducing concentrations. At higher polymer concentrations, one finds changes in the spectrum at large wavenumbers7. But these seem to be due to the onset of continuum viscoelasticity and are not per se an aspect of drag reduction).

The fibres used in our experiments were chrysotile asbestos, dispersed in a 0.5% aqueous solution of Aerosol OT, at a nominal concentration of 300 p.p.m. by weight. The experimental details are given elsewhere^{6,7} and the LDA and signalprocessing arrangements were as described in ref. 8. The onedimensional spectrum E(k), where k is the wavenumber, and

$$\bar{u}^2 = \int_0^\infty E(k) \, \mathrm{d}k$$

was put in dimensionless form using the relationship

$$\tilde{E} = \frac{E(k)}{2\bar{u}^2} R$$

where \bar{u}^2 is the mean-square fluctuating velocity and R is the pipe radius. The wavenumber was made dimensionless by multiplying by R.

The LDA relies on the scattering of laser light from small particles in the flow. Before discussing our results for energy spectra, we should consider the effect of light scattered from the suspended asbestos fibres (on the LDA signal). Our normal practice (for example, when working with polymer solutions) is to add scattering particles by seeding the flow with milk at a concentration of 100 w.p.p.m. The average size of the particles of fat in milk is $\sim 0.3 \,\mu\text{m}$ and this is small enough to follow the highest frequency turbulent fluctuations. Chrysotile asbestos occurs naturally in the form of macro fibres which are made up from basic fibrils with a mean diameter of ~40 nm (refs 9, 10). These macro fibres readily break down and in the specially prepared suspensions used here, the basic fibrils are preserved

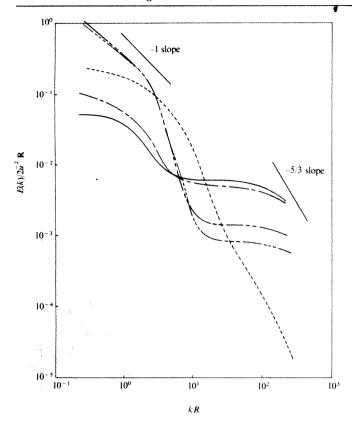

Fig. 1 One-dimensional turbulent energy spectra in a 300 p.p.m. asbestos fibre suspension at various levels of drag reduction, for $Re = 1.4 \times 10^4$: all spectra were measured at the centreline of the pipe. — Run 1, DR = 69%; ——— run 2, DR = 76%; ——— run 3, DR = 56%; ———— run 4, DR = 55%; ——— results for water.

with a very high aspect ratio⁹. It is difficult to measure the length of such fibrils directly but, although there is some disagreement between statistical methods, it is clear that the mean length-to-diameter ratio of individual fibrils in an undegraded suspension is in the range 10³-10⁴. Thus a contribution to the scattered light from individual fibrils might bias the LDA signal towards the lower turbulent frequencies. To assess this possibility, extensive tests were carried using various concentrations of milk, the surfactant and the asbestos fibres. In particular, we studied oscillographs of the 'burst' signals and spectra of the Doppler photocurrent. Details may be found in ref. 7 but we should mention two important conclusions here. First the Aerosol OT (presumably due to the naturally occurring micelles) was a satisfactory seeding material and milk was not needed. Second,

the fibrils did not contribute to the a.c. part of the LDA signal (that is, the part that gives the fluid velocity) but only to the d.c. or pedestal level (which determines the signal-to-noise ratio). From these tests we chose a nominal fibre concentration of 300 w.p.p.m. as giving large drag reductions with satisfactory signal-to-noise ratio for the LDA.

Some results for measurements at the pipe centreline are shown in Fig. 1, for several values of drag reduction (DR) and at one Reynolds number, $Re = 1.4 \times 10^4$. In each case, an experimental 'run' consisted of one pass of the whole amount of working fluid through the apparatus at a fixed Reynolds number. Further 'runs' were further passes of the same fluid at the same Reynolds number. The Reynolds number was calculated from the pipe diameter, the bulk mean velocity and the kinematic viscosity of water.

Figure 1 shows that spectra measured in the fibre suspension have a curious 'kinked' appearance; being reduced below the newtonian spectrum level at an intermediate range of wavenumbers (roughly corresponding to the inertial range). The position and extent of the 'reduced level' region was found to depend on the amount of drag reduction. This suggested that we were observing an interaction between the turbulent eddies in a particular wavenumber (or eddy-size) range and the suspended fibrils.

To test this idea the 'reduced level' region was characterized by an interaction wavenumber $k_{\rm m}$ which was calculated by noting the two wavenumbers marking the beginning and end of this region, and taking the arithmetic mean. Hence we obtained a mean interaction length scale $l_{\rm m}=k_{\rm m}^{-1}$. Values of $l_{\rm m}$ are given in Table 1 for various levels of drag reduction (DR) and at four different Reynolds numbers. These values range from $l_{\rm m}=0.84$ mm (corresponding to DR = 38%) to $l_{\rm m}=2.4$ mm (corresponding to DR = 76%). Clearly we should consider what relationship (if any) exists between: (1) $l_{\rm m}$ and some length scale associated with the individual fibrils; and (2) the amount of drag reduction and $l_{\rm m}$.

In considering the first point, note that $l_{\rm m}$ is a dynamic measurement of the length scale associated with fibrils actually interacting with the turbulent eddies. Thus there must be imponderable factors in a comparison with the length of fibrils

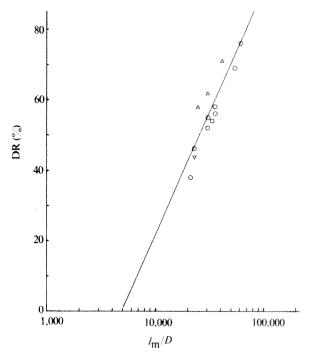

Fig. 2 Variation of percentage drag reduction (DR) with interaction length scale $(l_{\rm m})$ in a 300 p.p.m. asbestos fibre suspension. ∇ , $Re = 0.9 \times 10^4$; \bigcirc , $Re = 1.4 \times 10^4$; \triangle , $Re = 3.2 \times 10^4$; \square , $Re = 5.3 \times 10^4$.

either in a static suspension or (worse) evaporated out from such a suspension. Furthermore, there are considerable uncertainies in performing such measurements. Also the idea that the eddy interaction is with a mesh of entangled fibrils11 introduces the possibility of a length scale which is larger than any individual fibril.

Nevertheless, we may expect l_m to be related to the largest fibril lengths present in any appreciable fraction and measurements of length distribution in a similar suspension suggest a mean value of 1.4 mm for the longest fibrils 10. Thus we can reasonably claim that l_m is the correct order of magnitude for there to be a physical relationship to individual fibril length.

The second point was investigated by plotting values of drag reduction against the corresponding values of l_m . As can be seen from Fig. 2, the data points cluster quite well about a straight line. The variation with Reynolds number was not statistically significant and the single straight line was fitted using the least-squares method. The resulting relationship was found to be:

$$DR \times 100\% = \{0.70 \log_{10}(l_m/D) - 2.60\} \times 100\%$$

Finally, we previously remarked⁶ that the qualitative changes of turbulent structure in undegraded fibre suspensions agreed with a previous theoretical prediction¹². Note that the present results for spectra apparently support that theoretical picture. We seem to be observing a form of resonance phenomenon where the fibres are strongly excited by those turbulent eddies with spatial frequency roughly equal to the inverse of the fibril length. Thus, for once, a simple mechanistic model may well be relevant to the underlying physics of this intriguing effect.

We thank Turner Brothers Asbestos Co. Ltd for drag-reducing chrysotile asbestos suspensions.

²¹⁰Pb in surface air at Enewetak and the Asian dust flux to the Pacific

Karl K. Turekian & J. Kirk Cochran*

Department of Geology and Geophysics, Yale University, Box 6666, New Haven, Connecticut 06511, USA

As part of the SEAREX programme, an air filter system and a precipitation collector were deployed at Enewetak (11°20' N, 162°20' E). A description of the air filter system and initial results on the chemical composition of the collected aerosols¹ and on the organic components² have been reported elsewhere. As part of the same programme we have measured 210Pb (and ²¹⁰Po) in air filter and integrated monthly precipitation samples during 1979 to estimate the ²¹⁰Pb collected Aux $(0.15\pm0.02~d.p.m.~cm^{-2}~yr^{-1})$ and the Asian $(38\pm20~\mu g~cm^{-2}~yr^{-1})$ at this location in the Pacific. dust flux

²¹⁰Pb (22-yr half life) is a radioactive nuclide produced in the air by decay of gaseous ²²²Rn (3.8-day half life) emanating from continental soils. As ²¹⁰Pb is produced, it is scavenged by precipitation and its mean life with respect to removal from the atmosphere is \sim 5 days (see ref. 3 for a summary). If the primary

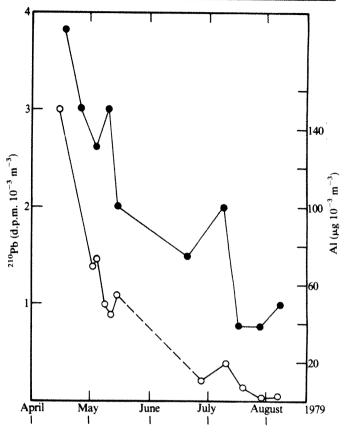

Fig. 1 210Pb concentrations (•) in air filter samples taken at Enewetak between April and August 1979. The Al data (O) from ref. 1 are also plotted.

source of ²¹⁰Pb in the aerosol is decay of atmospheric radon, then this short residence time precludes the presence of much ²¹⁰Po (138-day half life), the granddaughter of ²¹⁰Pb (the daughter being ²¹⁰Bi with a 5-day half life). Thus the ²¹⁰Po/²¹⁰Pb activity ratio in aerosols provides a way of determining the contribution of these nuclides from other sources with ²¹⁰Po/²¹⁰Pb activity ratios ≥1, such as continental dust and ocean surface and volcanic emanations. We have used 210Pb measurements to estimate the flux of other air-borne materials from the continents. Because its source is the Earth's surface rather than the stratosphere, as is the case for many cosmogenic and bomb-produced radionuclides, we believe that 210Pb is a better analogue of components injected into the troposphere.

The air filter samples were taken serially; some were used for the chemical assay and some for radiochemical analyses. The filters were dissolved for radiochemical analysis and ²¹⁰Po and ²¹⁰Pb determined using procedures described previously⁴. Our results are given in Table 1 and the ²¹⁰Pb data are plotted in Fig. 1. The monthly precipitation samples were collected as described by Benninger et al. (manuscript in preparation). Only the first seven samples of a year's collection were returned to the laboratory. The measurements (see Table 2) were made when ²¹⁰Po was virtually in equilibrium with ²¹⁰Pb. In all the air samples, the ²¹⁰Po/²¹⁰Pb activity ratios are statistically indistinguishable from 0. Thus the ²¹⁰Pb in the aerosols is derived from atmospheric 222Rn decay.

Although 210Pb is derived from atmospheric radon, there is a strong correlation between the aluminium concentration (representing the soil aerosol) and the ²¹⁰Pb concentration (Fig. 1). This relationship is also observed, to some extent, for the lipid fraction of the organic component of the air², implying that the aerosol sampled is a mixture of two parts—one derived from air rich in continental mineral and plant materials and high in ²²²Rn, and the other from air containing less of these components. Duce et al. have identified the former as dust from the Gobi Desert carried eastwards by high-level winds and

injected below the trade wind inversion east of Enewetak. The source of the air with low concentrations of all components must be the east, because of the predominantly easterly circulation.

Comparison of our Enewetak air filter results with observations made at Hawaii in 1971⁵ shows considerably higher values of ²¹⁰Pb at Hawaii. Between 15 May and 20 June 1979 at Enewetak, the concentration of ²¹⁰Pb was 1.5-2 d.p.m. 10⁻³ m⁻³. Between 30 May and 22 June 1971 at Hawaii, the values below the trade wind inversion were 3.4-19.4 d.p.m. 10⁻³ m⁻³ with a mean of 9.3, and above were 25.6-93.4 d.p.m. 10⁻³ m⁻³ with a mean of 46. Therefore the mean ²¹⁰Pb concentration in surface air at Hawaii is about five times greater than at Enewetak.

The use of ²¹⁰Pb to determine fluxes of continentally derived material requires an independent measure of the ²¹⁰Pb flux at the site. Direct measurements are not yet available for Hawaii but we have made a global model for the ²¹⁰Pb flux which can be used to estimate the flux around Hawaii³. This value is $\sim 1 \text{ d.p.m.}^{210}\text{Pb cm}^{-2}\text{ yr}^{-1}$. The ²¹⁰Pb flux at Enewetak has been measured using the monthly precipitation collections made during the year when the aerosol samples were taken. Although several precipitation samples were lost in transit we believe we can still reasonably estimate the flux from the recovered samples. Table 2a shows that although the monthly fluxes show variations, these are small and independent of season. The average of all the monthly fluxes yields an estimate of the annual ²¹⁰Pb flux of $0.15 \ (\pm 0.02) \ \text{d.p.m.}^{210}\text{Pb cm}^{-2} \text{ yr}^{-1}$ —a factor of seven lower than the Hawaii model flux estimate.

The apparent relationship between the mean concentration of ²¹⁰Pb in the air over a month's sampling and the monthly

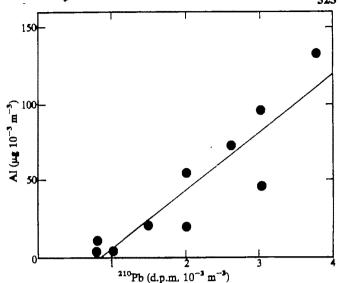

Fig. 2 Al versus ²¹⁰Pb in air filter samples from Enewetak 1979.

precipitation flux of ^{210}Pb is shown in Table 2b. The relationship can be used to estimate the mean annual concentration of ^{210}Pb (C) in the air based on the average ^{210}Pb flux (F). (The regression equation is $C[\text{d.p.m.} \quad ^{210}\text{Pb} \ 10^{-3} \ \text{m}^{-3}] = 4.7-21.4 \times F[\text{d.p.m.} \quad ^{210}\text{Pb} \ \text{cm}^{-2} \ \text{yr}^{-1}]$.) A mean ^{210}Pb flux of $0.15 \ \text{d.p.m.} \ \text{cm}^{-2} \ \text{yr}^{-1}$ corresponds to a mean air concentration of $1.5 \ \text{d.p.m.} \ 10^{-3} \ \text{m}^{-3}$.

It is evident from Table 2b that the ratio of ²¹⁰Pb flux to air concentration, which has the dimensions of a velocity (='total deposition velocity'), varies as a function of season. The dry season is characterized by a velocity of 1 cm s⁻¹ and the wet season by 4 cm s⁻¹. The total deposition velocity at Hawaii between 30 May and 22 June 1971 is ~3 cm s⁻¹. These values are comparable with that of ~4 cm s⁻¹ for the region around Bermuda (L. K. Benninger et al., in preparation) determined for the same time of year. All these oceanic sites have higher values than continental sites (ref. 3 and L. K. Benninger et al., in preparation). The air above the trade wind inversion is the source of most of the ²¹⁰Pb flux at subtropical oceanic sites because this air has trajected far over continents. When the serosols above the trade wind inversion are supplied to the inversion, they are efficiently scavenged by precipitation resulting in lower 210Pb concentrations below the trade wind Inversion than above (see ref. 5). This causes the total deposition velocity, measured at sea level, to be higher than that measured above the trade wind inversion. Strong mixing over continents tends to homogenize the lower air ²¹⁰Pb concentration, thus yielding a lower total deposition velocity. We believe that the high deposition velocity given by the 210Pb data at the ocean surface should be used to obtain fluxes of material derived from

Table 2 a, 210Pb in rain at Enewetak (April-November 1979) and b, relationship between 210Pb in air and 210Pb precipitation flux

For the rain samples ²¹⁰Pb was calculated from ²¹⁰Po measured 13–22 months after collection, assuming no initial ²¹⁰Po and ²¹⁰Bi activity = ²¹⁰Pb activity. Area of collector for ²¹⁰Pb flux = 183.4 cm².

continents on the premise that the same processes apply to all components derived from the continental surface.

By combining the measured ²¹⁰Pb flux and the aerosol ²¹⁰Pb and Al concentrations, we can directly estimate the flux of air-borne dust at Enewetak. Comparing the Al and ²¹⁰Pb curves of Fig. 1 shows that the trends are coherent and that a correlation between the two variables exists. As the filter samples analysed for 210Pb and Al were taken serially, it is possible, by interpolation, to estimate the Al concentration corresponding to each of our ²¹⁰Pb measurements using Fig. 1. The resultant plot is shown in Fig. 2. A linear regression of Al against ²¹⁰Pb yields a slope of 38 µg Al per d.p.m. ²¹⁰Pb with a y intercept of -32 µg Al and a correlation coefficient of 0.91. We believe this represents a mixing curve between high ²²²Rn (and therefore ²¹⁰Pb), high Al air and low ²²²Rn, low Al air. The ²²²Rn/Al ratio of each of the end members is obviously different as the regression line of Fig. 2 does not go through the origin.

Using the relationship shown in Fig. 2, we can determine the atmospheric flux of aluminium if we know the flux of 210 Pb, F_{210pb} , and the mean ²¹⁰Pb concentration in the air, $\lceil ^{210}$ Pb], as

$$F_{Al} = \left(S + \frac{y}{[^{210}Pb]}\right)F_{210Pb}$$

where S is the slope (38 μ g Al per d.p.m. ²¹⁰Pb) and y the y intercept in units of μ g Al 10^{-3} m⁻³ (= -32).

Assuming that the mean concentration of ²¹⁰Pb in Enewetak air is ~ 1.5 d.p.m. 10^{-3} m⁻³ during wet and dry seasons as discussed above, the Al flux at Enewetak is 2.5 µg Al cm⁻² yr⁻¹. An aluminium concentration of the dust component of 6.5% as used by Duce et al.1 corresponds to 38 µg dust cm⁻² yr⁻¹ for Enewetak. The uncertainties in all the components of the calculation are significant. We estimate therefore that the (1σ) uncertainty could be as much as $\pm 20 \,\mu g$ dust cm⁻² yr

Duce et al. estimate the annual flux of dust to the region around Enewetak by multiplying the measured monthly flux for late April and May (4 µg cm⁻² per month) by 3-4 on the basis of dust frequency information. This yields a flux of ~12- $16 \mu g \text{ cm}^{-2} \text{ yr}^{-1}$, a factor of 2-3 lower than our estimate.

A calculation of wind-blown detrital flux for the latitude of Hawaii can be made in a similar fashion to that for Enewetak. If we use the model ²¹⁰Pb flux for Hawaii, and assume that the same air mass end members as at Enewetak are involved, a mean ²¹⁰Pb atmospheric concentration of 9.3 d.p.m. 10^{-3} m⁻³ yields a flux of 35 µg Al cm⁻² yr⁻¹, equivalent to a dust flux of 530 µg cm⁻² yr⁻¹ (assuming 6.5% Al). This is about 14 times higher than that predicted for the latitude of Enewetak and shows the dominant influence, at the latitude of Hawaii, of the westerlies carrying radon and dust from Asia. Both Enewetak and Hawaii are far enough from the land sources that the dust will be dominated by the small sizes and therefore subject to removal by the same processes as those for indigenously produced ²¹⁰Pb. Based on our calculated dust fluxes, the sediment accumulation rates should be higher at the latitude of Hawaii and northwards than at the latitude of Enewetak. This does not seem to be the general case although there are few data for this region^{6,7}, implying that either our assumptions about the broad applicability of the relationship of Fig. 2 are invalid or there has been redistribution of sediments after deposition from the atmosphere but before final accumulation. The evidence for a strong atmospheric flux from the Gobi Desert supports the latter alternative. A more detailed analysis of sediment accumulation rates in the North Pacific is needed.

This research was supported by the NSF grant OCE 77-12847 as part of the SEAREX programme. The logistic assistance of the Mid-Pacific Marine Laboratory at Enewetak is gratefully acknowledged.

Identification of polychlorinated dibenzofurans in environmental samples

Christoffer Rappe*, Hans Rudolf Buser†, David L. Stalling‡, Lawrence M. Smith‡ & Ralph C. Dougherty§

- * Department of Organic Chemistry, University of Umeå, S-901 87 Umeå, Sweden

- § Department of Chemistry, Florida State University, Tallahassee, Florida 32306, USA

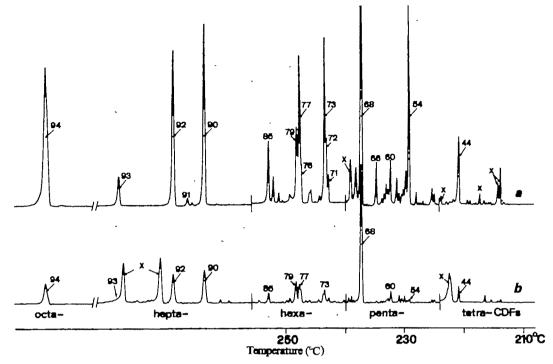

The polychlorinated dibenzofurans (PCDFs) are tricyclic aromatic compounds, which in chemical and toxicological respects are very similar to polychlorinated dioxins (PCDDs). The 2,3,7,8-tetra-, 1,2,3,7,8- and 2,3,4,7,8-penta-CDFs are extremely hazardous

compounds, they can be compared with the extremely toxic 2,3,7,8-tetra-CDD (ref. 1). PCDFs have been identified in PCBs at levels of 1-10 p.p.m., the major peaks being 2,3,7,8tetra- and 2,3,4,7,8-penta-CDF (refs 2-4). A large number of PCDFs and PCDDs occur as contaminants in chlorophenols⁵ and they have also been recognized and identified in fly ash and other incineration products at the p.p.b.-p.p.m. level⁸⁻¹¹. In 1968, 1,200 people in Japan were poisoned (Yusho disease) by a cooking oil contaminated by PCB12 and more than 50 PCDF isomers¹³. Liver samples from exposed patients were found to contain a highly reduced number of PCDFs, apparently many isomers were excreted or metabolized14. We report here the identification of a series of PCDF isomers in environmental samples.

Fat from the snapping turtle (Chelyda serpentina) obtained from the Hudson River (USA) and grey seal (Halichoerus grupus) from the Gulf of Bothnia (Haparanda, Sweden) were processed for PCDF analyses in two series of sequential chromatographic processes¹⁵. The turtle fat contained 750 p.p.m. of PCBs and the seal fat PCB concentration was $\sim 100 \text{ p.p.m.}$

Fat tissue (50-100 g) ground with sodium phosphate was applied to the first chromatographic system which contains a segment of potassium silicate and a segment of silica gel directly followed by a column containing carbon dispersed on glass fibres. The carbon adsorbs most multi-ring aromatic compounds and the major portion of biological co-extractives are not retained. The PCDFs, PCDDs and similar chemicals are then removed from the carbon by reverse elution with toluene. The toluene is removed and the sample is redissolved in hexane and applied to two columns in tandem. The first column contains both sulphuric acid dispersed on silica gel and caesium silicate. The eluate from this column passes directly into the second column that contains alumina.

Fig. 1 NCI Mass fragmentograms (m/e 306, 340, 374, 408 and 442) of a, Hudson turtle and b, Baltic seal sample showing elution of tetra, penta-, hexa-, hepta- and octa-CDFs; 50 m OV-17 glass capillary column. For peak identifications see Table 1; X denotes components other than PCDFs.

The purified extracts were directly used for GC-MS analysis. Aliquots (2 µl) corresponding to 0.1 and 0.8 g of fat of the snapping turtle and grey seal, respectively, were injected into 50-m glass capillary columns (OV-17 and Silar 10 c) leading directly into the ion source of a mass spectrometer operating in the negative chemical ionization (NCI) mode using methane as reactant gas. PCDFs exhibit intense negative molecular ions (M⁻). Some fragmentation occurs through addition of H and loss of CI with formation of (M-34) ions.

Mass specific detection (mass fragmentography) was used to detect PCDFs in these samples by selective monitoring of $(M+2)^-$ ions at m/e 306 (tetra-), 340 (penta-) and so on. More highly chlorinated PCDFs give response at the m/e values for the less highly chlorinated species due to the $(M-34)^-$ fragmentation. Quantification was based on peak height measurements and comparison with known quantities of authentic standards (2,3,7,8-tetra- and octa-CDF). Minimum detectability was 0.2 pg and 0.5 pg for 2,3,7,8-tetra- and octa-CDF, respectively. The same response for all isomers of a particular PCDF was assumed, because quantitative standards are not available. Responses for penta-, hexa- and hepta-CDFs were interpolated from the responses of tetra- and octa-CDF.

Complete NCI mass spectra (m/e 80–500, 1.4 s per scan) were recorded for the major peaks. Identification of a PCDF was based on the proper M^- ions and intensities of the ion clusters due to the Cl isotopes. Isomer identifications were based on the retention times on both OV-17 and Silar 10 c capillary columns and comparison with retention times of authentic standards.

In spite of differences in the geographical and biological origin, the samples show good correspondance. Figure 1a shows the mass fragmentograms of the turtle fat. Using the requirements discussed above, 18 different PCDF isomers could be identified (see Table 1). The total amount of PCDFs was estimated as 3 p.p.b. (Table 2). Of the individual PCDF isomers, the amount of 2,3,7,8-tetra-CDF was 45 p.p.t. and that of 2,3,4,7,8-penta-CDF was 620 p.p.t.

Figure 1b shows the mass fragmentogram of the seal fat, and the isomers identified are given in Table 1. These levels were much lower than in the turtle fat, the total amount being 40 p.p.t. The amount of 2,3,7,8-tetra-CDF was 1 p.p.t. and that of 2,3,4,7,8-penta-CDF was 15 p.p.t.

In the two samples the major PCDFs were 2,3,7,8-tetra-1,2,4,7,8- and 2,3,4,7,8-penta-1,2,4,6,7,8-, 1,2,3,4,6,7,8- and 2,3,4,6,7,8-hexa-1,2,3,4,6,7,8- and

1,2,3,4,6,8,9-hepta- and octa-CDF (see Fig. 1, Table 2). These isomers were also found to be the major PCDFs in commercial PCBs such as Aroclor 1254 and 1260 (ref. 4). However, in these commercial products some additional PCDFs were present; in the environmental samples these isomers (1,2,3,4,8- and 2,3,4,6,7-penta- and 1,2,3,4,6,7-hexa-CDF) were absent or present at much reduced levels. No such isomers were found in the study of the post-exposure tissue samples of Yusho patients, excretion or metabolism of these isomers was suggested.

The major PCDFs in commercial pentachlorophenols are 1,2,4,6,8-penta- and 1,2,4,6,8,9-hexa-CDF (refs 5-7). The former isomer was not found at all, and the latter was found at a very low level in these environmental samples. The isomer distribution of the PCDFs was also different from that reported in fly ash or PCB pyrolysates—notably differences in the

Table 1 PCDF isomers found in fat samples of the snapping turtle (Hudson River) and grey seal (Gulf of Bothnia)

Identification by retention times on two columns only.

Table 2 Amounts of PCDFs found in fat samples of a snapping turtle (Hudson River) and a grey seal (Baltic)

Turtle (pg per g)	Seal (pg per g)
45	1
820	15
700	8
1,000	10
350	3
3,000	40
	45 820 700 1,000 350

hexa- and hepta-CDF range11. The 1,2,3,4,6,8-hexa- and 1,2,3,4,6,7,9-hepta-CDFs are both dominant in the fly ash samples and PCB pyrolysates while they are absent or nearly absent in these fat samples. In contrast 1,2,3,4,6,8,9-hepta-CDF, a major isomer in the fat samples, is only a minor isomer in fly ash and PCB pyrolysate. Consequently the major source of the PCDFs in the fat samples of the snapping turtle and grey seal is probably a direct contamination by PCBs.

Earlier attempts to identify PCDFs in the environment were unsuccessful due to the lack of sensitivity of the analytical techniques16 and the lack of selective contaminant enrichment procedures¹⁵. To our knowledge this is the first identification of the highly toxic 2,3,7,8-tetra- and 2,3,4,7,8-penta-CDF in environmental samples.

Indigenous ¹³C-NMR structural features of soil humic substances

Brian L. Worobey & G. R. Barrie Webster

Pesticide Research Laboratory, Department of Soil Science, University of Manitoba, Winnipeg, Manitoba, Canada R3T 2N2

13C-NMR has recently been used to characterize the structure of soild humic and fulvic acids1-7. However, these studies all used the classical NaOH extraction followed by acid precipitation (humic acids precipitate, fulvic acids are acid and base soluble) to isolate humic substances. There has been concern⁸⁻¹⁰ over the chemical alteration of such isolated acids. The studies reported here describe the effects of mild extraction techniques compared with the classical isolation procedure. Fractions were characterized by IR spectroscopy and 13C-NMR. In addition, IR and ¹³C-NMR spectra of hemicellulosic components, extracted by the classical procedure from cellulose, are compared with spectra of humic and fulvic acids isolated by the same procedure. These spectra elucidate the effect of extractants on aromaticity, paramagnetic coextractives effects on spectra quality, and spectral evidence for a cellulose component as an integral part of humic substances.

Numerous attempts have been made to devise a structural formula representative of humic and fulvic acids11. Much of the difficulty may lie in the techniques used to isolate humus substances; these are often so severe (0.5 M NaOH extraction, concentrated HCl precipitation, HCl/HF purification) as to preclude the isolation of indigenous compounds.

For complex compounds, such as humic substances, the molecules may consist of rapid and mobile regions in which only long transversal relaxation times, T_2 , predominate to be observable as broad linewidths in a high resolution spectrum. Longitudinal relaxation times, T_1 , will be even longer as T_1 is always greater than T_2 . Consequently, caution is required when deriving concentrations of carbon classes from intensities of the signals or in deducing from the absence of a signal the essence of a specific structure. Low signal-to-noise ratios are common in humic spectra due to multiple causes of line broadening.

Humic acids extracted at different pH values exhibited an increase in aromatic protons (1H-Fourier-transformed (FT)-NMR) as pH decreased from 14.0 to 4.5; however, aliphatic protons were always most abundant at any pH (65-81%)12 Additional studies have emphasized differences in ¹³C-NMR spectra based on nature of the extractant used to isolate humic and fulvic acids^{4,6,13}, and interpretation of chemical shifts especially in the 110-160 p.p.m. range. This range is classically assigned to aromatic carbon absorptions but there is evidence that alkenic carbon resonances may be present.

The isolation 17-20 of humic-like substances from plants has previously been reported¹⁸⁻²¹. Humic acids were extracted¹⁰ from humifying leaves and clover roots; IR spectra were almost identical to fulvic and humic acids isolated from soil.

Hemicelluloses are an important constituent of raw organic matter, especially in mineral soils (35% in wheat straw²²). They are typically extracted from wood with 40% NaOH followed by addition of acetic acid to the filtrate to yield the precipitate hemicellulose²³. Hemicellulose was first used to describe a product obtained from cereals with dilute alkali treatment and precipitation of the extract with acid24. The product was easily hydrolysed to give a mixture of sugars.

Cellulose contains hemicelluloses which are alkali soluble and precipitable with acid. Acid treatment can degrade the polysaccharides in hemicelluloses to furfurals. Glucuronic and galacturonic acids (associated with hemicelluloses) are degraded by 12% HCl to xylose and arabinose respectively; both of these subsequently degrade to furfural in the presence of acid21

We consider the non-destructive isolation, purification and analysis of humic acids from an agricultural soil. A precursor of humus substances was also analysed using the classical isolation procedure.

Soil (orthic black chernozem, 38% sand, 30% silt, 32% clay, 5.4% organic carbon) was extracted with 0.5M NaOH (aq) solution purged with nitrogen in a brown glass bottle and shaken for 6 h. Samples were centrifuged for 30 min at 13,000 r.p.m. The supernatant was filtered and the filtrate slowly acidified to pH 1.5 with concentrated HCl. The humic acid precipitate (I) was centrifuged; the pellet was dissolved in weak alkali and ultrafiltered on a Diaflo UM2 membrane (<1,000 molecular weight excluded) in a stirred cell to desalt and concentrate the humic solution. When the filtrate reached a pH of 6.5 and the volume was reduced to 500 ml, the retentate was shell frozen and lyophilysed. Humic acids were stored in a desiccator under vacuum. Fulvic acid was prepared from a separate soil sample using 0.5 M NaOH as described above, except that the alkali-acid soluble supernatant obtained after the humic acid centrifugation was ultrafiltered (UM2-Diaflo) and lyo-

Aqueous 0.02 M Na₄P₂O₇ was neutralized to pH 7 and used to extract the same soil to yield humic acid II. The second Na₄P₂O₇ extract was treated using acetone (1:1) to salt-out the humic acids (III) instead of acid precipitation. This precipitate (III) did not have to be dispersed with base for ultrafiltration as it was the sodium salt. Yields of humic acids were, 0.93 g (I), 0.57 g (II), and 1.47 g (III) per 500 g of soil respectively.

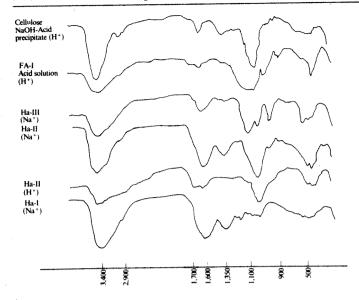

Fig. 1 Composite IR spectra of humic and fulvic acids and a cellulose component isolated in these studies (CM⁻¹).

The ratio of 1:1 acetone/water extract used for preparation of humic acid III was the minimum amount of acetone necessary for precipitation to occur. The supernatant from humic acid II did not yield any visible precipitate on addition of acetone (1:1) and humic acid III supernatant did not yield a precipitate on acidification to $pH\ 1-2$; therefore, the precipitates may be taken in each case to represent humic acids and not just a fraction of these.

IR spectra (Fig. 1) were generally diffuse and lacked coherent, well-defined resolution. However, at equal concentrations of humic acid analysed, absorption in the region of aromatic carbon (1,620 cm⁻¹ (ref. 26), and 1,690 cm⁻¹ (ref. 27)) decreased in intensity as: I>II » III. The fulvic acid IR spectra was most similar to humic acid III. This indicates the possible deformation of indigenous structure due to the acidification step.

step.

13C-FT-NMR spectra for humic acids, I, II, III, and a NaOH-extracted humic acid, precipitated, and exhaustively de-ashed humic acids (I-IV) are shown in Fig. 1. Aromatic/alkenic

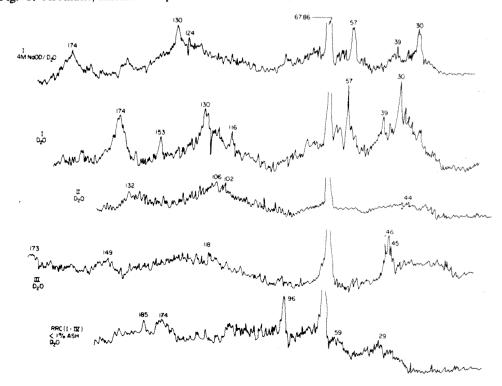

absorption in the 100-160 p.p.m. region increases (I>II>III) as the harshness of the extraction procedure increases, that is, when NaOH and HCl are used. This corroborates the IR evidence, which illustrated the same effect.

A humic acid, prepared from a Red River Clay soil (RRC I-IV, 40% sand, 16% silt, 44% clay, 4.4% organic carbon), with a very low ash content (0.1% ash) yielded a spectrum (Fig. 2) not much different in terms of broad and low intensity absorption when compared with higher ash content humic acids. The spectrum was most similar to that for fulvic acid (Fig. 3) and cation analysis showed these two humic substances to have the lowest concentration of Cu²⁺ and Fe³⁺ (Table 1). Although the concentrations were much lower than the other humic acids (I-III) they were still high enough to cause profound peak broadening (due to paramagnetic ion-induced relaxation). Concentrations as low as 6 p.p.m. of Cu²⁺ in a glycylglycine sample causes absorptions to almost disappear²⁸. Cu²⁺ concentrations were 52 and 114 p.p.m. for the fulvic acid and de-ashed humic acid respectively.

There were only slight differences between the spectra of humic acid I in D_2O solution compared with that in a 4 M NaOD solution (Fig. 2), indicating the lack of observable ($^{13}C\text{-NMR}$) alteration in the humic acid during radiation (\approx 48 h). Any alkaline degradation would have already occurred during the preparation of I.

For the humate extracted by 0.5 M NaOH, the peaks at 30.05, 38.96 and 57.52 p.p.m. fall in the range of aliphatic carbon absorption. According to Abraham and Loftus25 configurations for 30.05 p.p.m. would be R-CH₂-R or R₃C-R, while the bands at 38.96 and 57.52 p.p.m. could reflect R₂CH-R. The major peaks at 116.26 and 130.46 p.p.m. could be due either to alkenic or aromatic carbons. Early workers in ¹³C-NMR assigned the alkenic carbons to an absorption between 120 and 155 p.p.m., as opposed to a much broader aromatic region30, 13C-NMR of humic substances had generally assigned the area 110-160 p.p.m. to aromatic carbon 4,31 however, more recently the area of absorption of alkenic carbons has widened such that they cover a wider band than aromatic systems²⁹. Thus absorption in the 110-160 p.p.m. range could belong to either aromatic or alkenic carbons 32,33 Positive identification of two C-H aromatic carbons at 130 and 128 p.p.m. in a humic acid have been reported³⁴ and supported by the observation that on loss of proton decoupling the peaks split into doublets. Thus, in soil humic matter, there are some

Fig. 2 Composite of humic acid ¹³C-NMR spectra isolated by various extraction methods. ¹³Cvarious extraction methods. NMR spectra were obtained on a Brucker WS 900S Multinuclear NMR spectrometer operating at 22.63 MHz (35 °C). Free induction decays were digitized, accumulated and a Fourier transformation performed by computer. D2O lock and full proton decoupling were used during an accumulation of 80,000-100,000 scans using 90° pulse and total pulse delay and acquisition time of 1.589 s, pulse width = 14 µs, internal standard deutero-dioxane (67.86 p.p.m.), chemical shifts reported in p.p.m. resolution = ± 10 Hz(~ 5 p.p.m.).

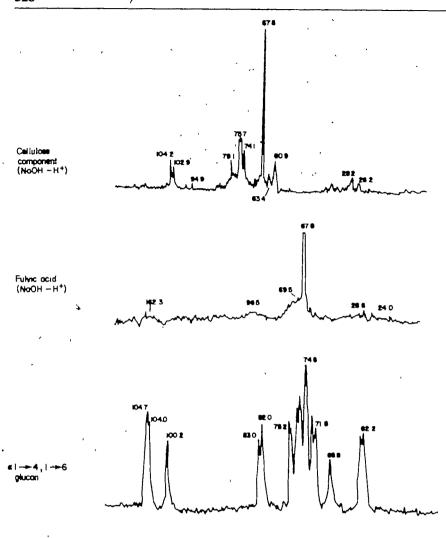

Fig. 3 ¹³C-NMR spectra of a fulvic acid, a cellulose component and a giucan, internal standard = d₆-dioxane (67.8 p.p.m.) all in NaOD/D₂O (1M).

¹³C-NMR absorptions that might be assigned to aromatic carbons.

A peak at 174.33 p.p.m. identified in our spectra agrees well with that reported elsewhere (174 p.p.m.); this can be attributed to carboxylic groups, esters and amides, but primarily to carboxylate entities.

The Na₄P₂O₇-extracted, acid-precipitated humic material (II) gave a ¹³C-NMR spectrum with a very high background noise level and very broad peaks (Fig. 2). This can be attributed to the high ash content, which include paramagnetic ions, principally Fe. There is a corresponding loss of information, with only three main absorption bands, 44.5 p.p.m. (aliphatic), 106.5 p.p.m. (alkenic or aromatic) and 132.12 (alkenic or aromatic).

The humic acid III spectrum (Fig. 2) suffered from the same defect, but sharp split peaks appeared at 40–47 p.p.m. Six-membered aliphatic rings also absorb partially in this region.

A humic acid precursor; cellulose, showed a visible precipitate on acidification of a basic extract, the yield being ~ 100 mg/per 50 g acid-washed cellulose; yields would have been higher for unwashed cellulose. Sucrose, glucose or galacturonic acid gave no precipitates using the classical extraction scheme.

The similarity of the cellulose precipitate to that of humic and fulvic acid revealed by the IR spectra (Fig. 1) is consistent with cellulose being an integral part of the innate structure of humic substances as well as a precursor.

¹³C-FT-NMR spectra revealed some similarity between the cellulose precipitate spectrum compared with the fulvic acid (Fig. 3) or humic acid IV (Fig. 2) spectra and hemicellulose component (Fig. 3)—an $\alpha 1 \rightarrow 4$, $\alpha 1 \rightarrow 6$ glucan³⁵ was reasonably similar to that of the cellulose precipitate (Fig. 3). NaOH (0.2 M) is an efficient extractant for polysaccharides from soil³⁶ and hence such hemicellulose components must be an integral part of the classical fractionation scheme.

Acid—base treatment of carbohydrates (glucose) yields aromatic compounds³⁷ even at pH 3.5, including dihydroxybenzenes and dihydroxybenzoic acids which are considered model monomers of humic substances. Although yields were low (3.5%) they may increase significantly in the presence of potential endogenous catalysts such as clays and transition metal cations. Solutions of carbohydrates in 0.63 M NaOH resulted in degradation to a large number of phenols including humic precursors³⁸.

The classical acid—base extraction scheme may artificially cause aromatic structures to form from indigenous carbohydrates. This would result in aromatic signals or absorptions in ¹³C-NMR, ¹H NMR and IR spectra. Note that the ¹³C-NMR spectrum for fulvic acid solution of polysaccharides in fulvic and humic acids extracted from sediments (Fig. 1) is very similar to that shown for the hemicellulose component isolated in our studies (Fig. 3).

Our studies suggest that humic substances may not be as aromatic as previously thought, that the extraction technique is very important in determining aromaticity that paramagnetic ions can be critical in determining spectral features, and that

Land plant evidence compatible with gradual, not catastrophic, change at the end of the Cretaceous

Leo J. Hickey

Division of Paleobotany, Smithsonian Institution, Washington, DC 20560, USA

Field study of the fossil and sedimentary record across the Cretaceous-Tertiary (K-T) boundary in Wyoming and Montana has been combined here with a reassessment of the published record of terrestrial palynomorphs to test recent hypotheses that a universal biotic catastrophe caused by an asteroid1-3, cometary impact4 or a supernova5 terminated the Cretaceous. Evidence from land plants is particularly critical because plants form the base of the terrestrial food chain. Thus, massive disruptions of the Earth's vegetation by the postulated effects of a cosmic disaster (blocking of solar radiation for several years by a dust cloud¹, severe atmospheric heating^{1,4,6,7} or ionizing radiation5) would have an amplified effect on the land fauna. However, I report here that the geographically uneven and generally moderate levels of extinction and diversity change in the land flora, together with the non-synchroneity of plant and dinosaur extinctions, contradict hypotheses that a catastrophe caused terrestrial extinctions.

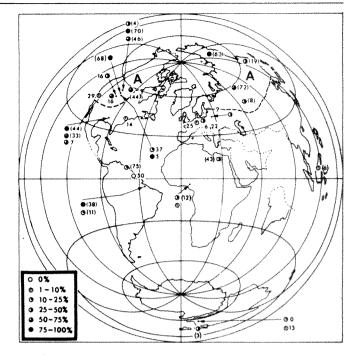

Fig. 1 Severity of plant extinction (mostly at the species level) and change in diversity across the Cretaceous-Tertiary boundary. The dashed line represents the approximate limits of the Aquilapollenites province (designated 'A') covering northwestern North America and northeastern Asia. The symbols for localities indicate the percentage of Cretaceous plants that became extinct across the K-T boundary, and are explained in the key. The figures accompanying the symbols indicate the percentage change in diversity with negative values indicated by parentheses. Levels of extinction >50% reported at two localities outside the Aquilapollenites province are attributable, in the case of the Mississippi Embayment, to facies changes 47 or restriction of the sample to the Normapolles group of pollen, which fared badly across the K-T boundary; and, in the case of northeastern Brazil, to a restricted sample of indicator species¹². (Base map for the early Palaeocene redrawn from ref. 48.)

Fossil plants, mainly palynofloras, provide a detailed picture of terrestrial change across the K-T boundary that has been sampled throughout much of the world. Unfortunately, this record does not yet offer the degree of time-stratigraphical resolution possible for the marine sequence because of the relatively few studies across the boundary, wide spacing of samples and frequent emphasis on recognition of the Cretaceous or of the Palaeocene using selected guide fossils rather than by characterizing the whole assemblage. In addition, shifts in sedimentation across the boundary are seldom documented but may strongly influence the floristic composition; megafossil remains have been extensively misidentified⁸⁻¹¹ and serious problems of correlation exist between marine and non-marine stratigraphical sections as well as between sections on different continents. Despite these difficulties, a coherent pattern of moderate floristic change can be discerned across the K-T boundary12

To standardize the extinction figures reported here, all late Maastrichtian forms not found in the Lower Palaeocene were treated as though they became extinct at the K-T boundary. These extinction figures were also based on geographically restricted floras which probably record local range changes as well as extinctions. Both these factors elevate the apparent level of extinction.

Late Cretaceous floras were dominated by the flowering plants, which appeared in the mid-early Cretaceous^{6,13-17} and achieved dominance by the Turonian^{6,18} in the Northern Hemisphere but perhaps not until the Maastrichtian¹⁸ in the Southern Hemisphere. During the mid-late Cretaceous, the pollen flora of the middle- and high-latitude Northern

Hemisphere gradually diverged into two distinct provinces^{19,20}. The area from eastern North America across Europe into western Asia was dominated by the Normapolles group. A second province extended from western North America nearly across Siberia and was characterized by forms of unusual morphology, known as the Aquilapollenites group^{21,22}, along with, for example, Wodehousia, Azonia and Proteacidites. Both pollen and leaf floras were dominated by archaic taxa with modern forms such as the palms, Nothofagus^{18,20}, Platanus^{23,24} and a few others^{20,25}, appearing in small numbers gradually through the late Cretaceous.

At the end of the Cretaceous, the most noteworthy change in the world land flora was the decimation of the Aquilapollenites province. Within its boundaries, extinction often amounted to 75% of the Cretaceous species and showed an imperfect pattern of increase towards the north (Figs 1, 2). Elsewhere the level of extinction was much less, seldom exceeding 50% of Cretaceous forms 12 . Floral diversity also decreased most markedly in the Aquilapollenites province with the level of diversity attenuation generally increasing northwards. Megafloral studies across the K-T boundary are limited to western North America but show similar levels of extinction of Cretaceous forms $(40-60\%)^{12}$ and a substantial increase in the proportion of toothed (that is, cooler climate 26,27) leaves.

For comparison, the same method of analysis was applied to extinction across the Palaeocene-Eocene boundary, where no catastrophe has ever been invoked. In North Dakota a third of the palynoflora²⁸ and one-half of the megaflora²⁹ became extinct through a section starting 10 m below the boundary. Similar levels of extinction are seen by comparing the total Clarkforkian (latest Palaeocene) with the total Wasatchian (early Eocene) megaflora of the Bighorn Basin in Wyoming (S. L. Wing, thesis in preparation, Yale University).

Given a terminal Cretaceous event of several to several hundred years duration and of overwhelming magnitude, extinctions in various terrestrial groups should appear synchronous at our resolution limits. Only in western North America have stratigraphical sections containing both the last dinosaurs and plants been carefully observed. There, the Cretaceous flora persists above the level of the highest unreworked dinosaur bone. In Alberta the floral change occurs 6 m higher³⁰. In east central Montana³¹, northwestern Wyoming (my observations and P. Gingerich, personal communication) and southeastern Wyoming³², the change occurs at a minimum of 2-3 m higher. In Colorado the change lies an unspecified distance above the last dinosaur³³. Based on a sedimentation rate of 65 m Myr⁻¹ for the Edmonton Group³⁴, the stratigraphical interval between the last dinosaur and the floral change would represent $\sim 50-90 \times 10^3$ yr. In addition, several authors note an attenuation in dinosaur

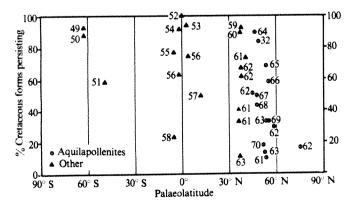

Fig. 2 Survival of Cretaceous plant species across the K-T boundary as a function of palaeolatitude. Localities falling in the Aquilapollenites province have been distinguished from those in other regions. Reference numbers appear beside the points. Note the generally high levels of floral survival from high-southern to mid-northern palaeolatitudes.

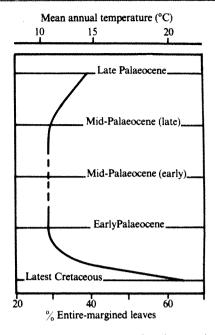

Fig. 3 Changes in the percentage of entire-margined, dicotyledonous angiosperm leaves and inferred palaeotemperature changes from the latest Cretaceous through the Palaeocene in the Bighorn Basin of northwestern Wyoming (modified from ref. 72).

abundance and diversity towards the boundary^{31,34}, a finding corroborated by my field work in north-west Wyoming.

Generally moderate, geographically variable levels of landplant extinction and the lack of synchroneity in plant-dinosaur extinctions at the close of the Cretaceous make it unlikely that a universal biotic catastrophe occurred. Despite a lower thermal gradient in the Cretaceous^{35,36} due to lack of polar ice caps³⁶ and a generally higher average Earth temperature³⁷, Northern Hemisphere floras show an increase of cooler-temperature forms with increasing latitude³⁷, though more gradually than at present. This suggests a correlative increase in the efficiency of plant dormancy mechanisms as well as chromosomal redundancy, both of which would have raised resistance to environmental stress³⁸⁻⁴⁰. The elevated levels of extinction seen at higher northern latitudes across the K-T boundary effectively contradict the assertion that the Earth's vegetation was simply able to regenerate after cosmic catastrophe^{4,5}. In addition. low-latitude floras, relatively lacking in such dormancy and carryover mechanisms, suffered least, exactly the opposite of that expected from the catastrophic model (Figs 1, 2).

Alternatively, the pattern of change in land plants, the increasingly cooler affinities of latest Cretaceous to early Palaeocene palynofloras 36,41-44, the increase in the percentage of forms with toothed leaves in the western United States11 attenuation of dinosaurs and the lack of synchroneity in extinction of plants and dinosaurs are compatible with climatic cooling. A palaeotemperature curve for Montana and northern Wyoming suggested by megafloral evidence (Fig. 3) and numerous marine palaeotemperature curves point to climatic cooling across the boundary with gradual recovery in the Palaeocene. (Recent suggestions of a very short-term temperature increase at the boundary 6.7.45.46 cannot be seen at the time scale of the floral studies reviewed here.) An attenuated dust cloud, rather than the completely opaque one of Alvarez et al., would have caused relatively less light to reach high latitudes due to the greater screening power of dust at the increasing angles of insolation that occur there. The result would have been a steepened gradient of declining temperatures towards high latitudes and an attendant increase in plant extinctions. However, the effect of such a dust cloud would have been of very short duration. Furthermore, this hypothesis fails to account for the lack of appreciable extinction or diversity decline at high southern latitudes (Figs 1, 2) or the irregular occurrence of such effects elsewhere. These are more satisfactorily explained by long-term climatic deterioration, whose influence would be far less uniform over the Earth's surface than that of a dust cloud.

The asteroid hypothesis has stimulated discussion between physical scientists and palaeontologists. However persuasive and well documented the evidence for an iridium anomaly, the connection between it and the terminal Cretaceous extinctions is tenuous at best. Before a general theory explaining these extinctions can be framed, additional data on geochemical causes of the Ir anomaly, the range of physical consequences of a postulated cosmic catastrophe, and the timing and magnitude of late Cretaceous extinctions must be gathered and evaluated.

Discussions with, though not necessarily concurrence of, Scott L. Wing, David Archibald, Bruce Tiffney and Walter Alvarez are gratefully acknowledged.

Spherical phosphatic microfossils from the Silurian of North Greenland

R. J. Aldridge & H. A. Armstrong

Department of Geology, The University, Nottingham NG7 2RD, UK

We report here that during routine micropalaeontological processing of Siberian limestone samples from North Greenland, a large number of small spherical, spinose microfossils have been isolated. These are comparable with forms studied in thin section by Sannemann¹, which have been referred to the group Acritarcha, erected by Evitt² to accommodate hollow, organicwalled microfossils whose affinities are uncertain. Our material suggests that the walls of the spherical bodies were minerialized rather than organic, throwing doubt on an assignment to the

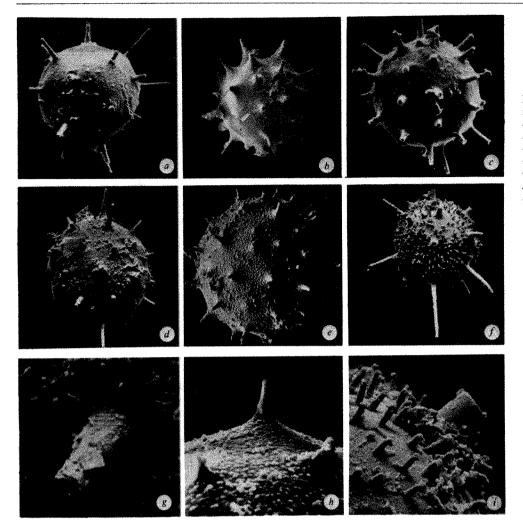

The specimens we have examined are from the upper part of the unnamed Silurian limestone formation and the unnamed Silurian black shale formation3 of Central Peary Land and their equivalents in Washington Land⁴, North Greenland. The samples were collected by field geologists of the Geological Survey of Greenland and processed in dilute acetic acid at Nottingham to recover conodonts, other phosphatic microfossils and organic microfossils. Five samples (GGU sample nos 216849, 216853, 228978, 229036 and 228926) have yielded a total of more than 3,000 microspheres; associated conodonts include Pterospathodus celloni (Walliser) and indicate a late Llandovery age³. Samples processed using standard palynological techniques (involving the use of hydrochloric and hydrofluoric acids) for the recovery of organic-walled microfossils have failed to yield any similar bodies.

The size of the microspheres varies from 100 to 400 µm in diameter, and long spines, which are broken on almost all specimens, project from the surface (Fig. 1). The density of these spines is variable and their basal insertion ranges from parallelsided on some specimens (Fig. 1a) to broadly flaring in others (Fig. 1b). The central body may be smooth (Fig. 1a), granular (Fig. 1e, h) or covered with pillars up to 10 μ m long and 2 μ m in diameter (Fig. 1f, t). Scanning electron microscope examination of broken specimens has revealed several with complex wall structures (Fig. 2b-d). Commonly, an outer, thin, single layer is separated by 5–17 μ m from a double inner layer by stout pillars. On one specimen (no. MGUH 15322) we have observed a third inner, structureless layer (Figs 2b, c, 3b). Each wall layer except the latter is composed of crystallites arranged perpendicular to the surface (Fig. 2a, c) and is less than $1 \mu m$ thick. The spines arise from the inner layer (Fig. 2d) and also commonly display a double wall; the lower portions of the spines seem to be hollow (Fig. 2a, d). Although some of our specimens show simpler wall structures, this may be the result of removal or non-fossilization of the outer layers.

Energy dispersive analysis of the spheres showed high calcium (Fig. 3c, d) and high phosphorus (Fig. 3e, f) content of the outer surface and of the inorganic wall layers, indicating that they are composed of apatite. Repeated 20-s counts of the PK α and $CaK\alpha$ peaks on two microsphere specimens provided Ca:Pratios of 1.99 and 2.12, respectively. Two apatite standards

Specimen MGUH 15320, ×130. g, Specimen MGUH 15318, ×1368, showing spine insertion and partial breakdown of outer layer round spine. h, Specimen MGUH 15319, ×645. i, Specimen MGUH 15320, ×515. The pillared and granular 'ornament' on these specimens may represent the remains of the pillar supports of the outer wall, which has not been preserved. All specimens are from GGU sample 216849 numbers relate Geologisk collections of the Museum, Copenhagen.

analysed at the same time yielded ratios of 1.88 and 2.10 and a coeval conodont specimen, composed of organically secreted apatite, showed a ratio of 2.19. Published analyses of apatite are mostly in the same range $^{6.7}$, although our specimens seem to fall outside the range of francolite (Ca:P 2.5–2.7), a common diagenetic carbonate apatite in sedimentary environments 8 . The third inner layer of specimen MGUH 15322 produced no peaks on energy dispersive analysis, which is sensitive to elements with an atomic number of $\geqslant 11$. It is probable that this layer is organic in composition.

In assessing the biological affinities of the microspheres it is important to determine that the phosphatic mineralization of the walls is primary, and not a result of replacement during fossilization. Unfortunately, there is no unequivocal criterion. Circumstantial evidence is provided by the fact that there is very little phosphate in our limestone samples and that calcareous crinoid and brachiopod fragments show no signs of phosphatization. A chitinozoan (with an organic wall of 'pseudochitin'), from the sample with the most abundant microspheres, shows minor silicification and no trace of calcium phosphate. Hence, if the phosphatization is secondary, it has been extremely selective and mineralogically unusual. The phosphatic wall structure of the spheres is comparable with that of other phosphate-secreting organisms, such as lingulid brachiopods9, and it is more probable that the apatite is primary. However, some features of surface sculpture may be the result of

The shape of the microspheres is very similar to that of acanthomorphic acritarchs, which are normally smaller (average diameter $30~\mu m$) and have organic walls. Sannemann¹ assigned his specimens from the Devonian of the Frankenwald, West Germany, to the genus Hystrichosphaeridium on the basis of the general similarity in morphology. Subsequently, they were

transferred to the genus Baltisphaeridium^{10,11} and were catalogued as acritarchs by Eisenack¹². He noted, however, that they were unusually large and seemed to be constructed differently from the 'true' acritarchs. These structural differences are emphasized by our material and the phosphatic walls firmly rule

out classification with the acritarchs. Spinose, spherical skeletons are also common among the Radiolaria¹³, but their walls are latticed, spongy or perforate, and we know of none that compare closely in structure with the microspheres. Modern radiolarians have skeletons of opaline silica, although this may be replaced by other minerals in fossil material.

Somewhat similar structures are shown by microgranular foraminifera referred to the superfamily Parathuramminacea especially the genera Parathurammina, Archaesphaera and Uralinella. These, however, lack the perfect sphericity and complexity of wall structure shown by the microspheres, and preservation in phosphate would demand replacement of the original calcium carbonate tests. Finally, there is some similarity between our microspheres and various spherical calcium carbonate microfossils that have been termed calcispheres11 particularly those referred to the radiosphaerid calcispheres16 The structure of radiosphaerid calcispheres is rather different, as they are characterized by a spinose or prismatic outer wall layer, and again, preservation in phosphate would demand diagenetic replacement. However, the calcispheres are a heterogeneous group of uncertain affinities, and it is possible that specimens comparable to the Greenland microspheres have, at some time, been assigned to that group. Even so, there is no known group that readily accommodates our specimens. Their spherical structure, multiple concentric wall layers and prominent spines are characteristic, and their probable original apatite composition sets them apart from other microfossils. For ease of reference, we informally name them mazuelloids; the name is derived from the mediaeval latin term for 'mace'.

We report the results of our preliminary studies of these microspheres in the hope that they will stimulate finds of more material. The mazuelloids are probably widely distributed, but commonly missed in micropalaeontological investigations. They would not be preserved in palynological residues as they collapse in hydrochloric and hydrofluoric acids, and their small size and delicacy may lead to them being overlooked or broken in routine microfossil searches. Indeed, since recovery of the Greenland material, we have isolated several additional phosphatic mazuelloids from the upper Silurían of Czechoslovakia.

We thank Drs J. M. Hurst and J. S. Peel, of the Geological Survey of Greenland, for making the samples available for study. Mr A. Swift found the first specimens; photography and analysis were carried out at the Wolfson Institute for Interfacial Technology with Mr L. Green providing assistance. We also thank Mr K. J. Dorning, Dr P. J. Hill and Dr B. K. Holdsworth for valuable discussions and Professor C. Downie for reading the manuscript and suggesting improvements. H.A.A. acknowledges the award of a NERC Research Studentship. This article is published with the permission of the Director of the Geological Survey of Greenland.

ESR-dating of the fossil hominid cranium from Petralona Cave, Greece

G. J. Hennig*, W. Herr*, E. Weber† & N. I. Xirotiris‡

*Institut für Kernchemie der Universität zu Köln, Zülpicher Strasse 47, 5000 Köln-1, FRG

†II. Physikalisches Institut der Universität zu Köln, Abteilung für Metallphysik, Zülpicher Strasse 77, 5000 Köln-41, FRG ‡Institut für Anthropologie der Universität Frankfurt. Siesmayerstrasse 70, 6000 Frankfurt am Main, FRG

The age of the hominid cranium discovered in 1960 in a limestone cave near Petralona (Greece) is a continuing cause of controversy. The age of the skull, which was apparently encrusted by brown calcite soon after the death of the individual concerned, has been variously estimated at between 70,0001 and 700,0002 yr. Here we show using electron spin resonance (ESR) measurements of the calcite encrustation and of bone fragments that the age of the Petralona hominid lies between 160,000 and 240,000 yr. We also demonstrate, by trace element analysis, that the composition of the calcite encrustation is the same as that of the very top of the travertine floor.

Part of the difficulty in interpreting the Petralona skull stems from the circumstance of its discovery, on the floor of the cave. The cave fauna has been variously attributed to the Riss/Würm³ and Günz/Mindel4 interstadial, suggesting that the hominid might be classified as Homo sapiens neanderthaliensis or Homo erectus. It is, however, questionable, whether faunistic remains

can be related to the hominid cranium. Previous estimates of the age have been based on measurements of speleothem samples either from other branches of the cave or from deeper (and thus older) strata. We believe that only the skull itself and its encrustation should be the basis for absolute age determination.

After inspecting the calcite encrustation, which was removed from the well preserved skull by J. W. Melentis (University of Saloniki, Greece) and one of us (N.I.X.), our attention was directed to some larger speleothem samples that were collected a few years ago in the cave near where the skull was discovered. As expected, some of these travertine samples were covered by a thin, opaque, reddish-brown, non-laminated calcite layer resembling the coating on the skull. The lack of any lamination indicates only one uninterrupted depositional event. To confirm the assumption of an identical growth horizon, pieces of the skull encrustation (a) and of the calcite layer (b) covering some of the larger speleothem fragments were analysed for several trace elements by instrumental neutron activation analysis (INAA). For comparison, a calcite sample (e) from 30-40 mm beneath the surface layer of the travertine floor was included.

Comparison of the results in Table 1 clearly shows the high similarity of samples (a) and (b). Sample (e) is quite different.

The higher K-, Mn- and Na-contents of sample (b) compared with (a) can be explained by an increased fraction of clay minerals. The similarity of (a) and (b) with respect to most of the analysed elements implies that both belong to the same layer of deposition⁵. This result is significant because practically all previous age determinations⁶⁻⁹ were done on samples from deeper strata (as, for example, sample (e)), but not from the thin brown top layer (b) of the travertine floor. These earlier works on Petralona speleothems attempted to correlate the massive base calcite stratum of the floor with the skull itself. However, a reliable stratigraphy with respect to the cranium has never been established. Consequently, a definite dating of this hominid was not possible.

For the present study, five different samples with clear stratigraphical relations to the hominid skull were chosen:

- (a) Calcite encrusting the hominid skull, which should yield a lower age limit for the hominid.
 - (b) Top calcite layer covering the floor.
- (c) Bone fragments of the hominid skull, which had accidentially come loose with the calcite encrustation (a).
- (d) Calcite 3-4 mm beneath the surface layer (b), which should yield an upper limit for the hominid.
- (e) Calcite 30-40 mm beneath the surface layer (b). We considered that it was essential not to investigate only the small bone fragments of cranium (c), because although dating of animal and human bones by ESR has been reported to, bones may suffer from recrystallization and the hydroxylapatite can partially convert into fluorine-apatite. Calcite, however, is generally accepted as a stable mineral and a 'closed system'.

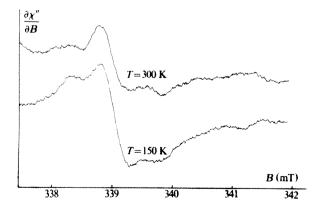

Fig. 1 ESR-spectra of bone fragments (c) of the Petralona hominid cranium, taken at 300 K and 150 K. $\nu = 9.5$ GHz, p = 3.7 mW, m = 50 mg.

Table 1 Trace element contents of calcite samples (a), (b) and (e), related to the hominid skull from Petralona Cave

Element	(a) (p.p.m.)	(b) (p.p.m.)	(e) (p.p.m.)
As	0.5	2.8	7.9
Co	1.7	1.3	0.02
Cr	13.3	14.3	0.32
Cs	1.9	1.1	0.01

Sc	1.17	1.01	0.05
Th	1.84	1.39	<0.03 ≤0.1

Trace element concentrations determined by instrumental neutron activation analysis (INAA). There were two successive neutron irradiations of 3 min and 12 h: thermal neutron flux was 8×10^{13} neutrons cm⁻² s⁻¹. Sample weights were ~150 mg, and average errors $\pm 10\%$.

Of the modern techniques such as thermoluminescence $(TL)^{11,12}$, electron spin resonance $(ESR)^{13-15}$ and uranium series dating 16-18, which are suitable for dating Quaternary calcites, ESR seemed to be the most advantageous for the following reasons: (1) The presumed ages of all samples are beyond the limits of radiocarbon dating. (2) Only milligramme amounts of most samples were available, so that the low U content (<1 p.p.m.) precludes the use of 230 Th/ 234 U-dating. (3) The high opacity of the bone and of some calcite samples is disadvantageous for TL-dating. The presence of a small clay fraction (of the order of a few parts per thousand) would cause strong interference with the TL-signal 11. The principle of ESR-dating has been described in detail elsewhere 10,13-15. In brief, ESR measures the concentration of paramagnetic electrons in defects of the crystal lattice, created by interactions with the natural radiation since the time of (speleothem) deposition. In the present study, ESR measurements were performed by means of a 'Bruker' spectrometer (BER 420) at a microwave frequency of 9 GHz (X-band) and a typical microwave power of 2 mW. The weighed samples were positioned in a variable, homogeneous magnetic field of $\sim 300 \text{ mT}$.

For ESR-dating, ~ 1 g of each sample was cleaned from the adherent clay or bone impurities, ground, etched for 10 min in 0.1 M HCl and separated from the fine-grain fraction by decanting off the supernatant, milky solution. Portions of identical weight (generally 50–150 mg) were exposed to different γ -doses between 10 and 100 krad (1 krad = 10 J kg⁻¹) using a calibrated 6,000 Ci (1 Ci = 3.7 \times 10¹⁰ s⁻¹) ⁶⁰Co γ -source. One portion of each set of samples was left unirradiated to obtain the ESR-signal of the natural radiation dose, that is the 'archaeological' dose. The γ -irradiated samples were either left to stand for at least 1 day or were kept at 100 °C for 1 h to remove the interfering (unstable) ESR signal, which presumably corresponds to the \sim 80 °C TL glow peak.

The specific ESR-signal (proportional to the radiation dose) was sometimes subject to interference from other resonances which did not increase linearly with γ -doses (that is, it showed strong saturation effects). This problem was overcome by lowering the temperature of the sample to $\sim 150 \, \text{K}$ using a helium gas-flow cryostat. At this temperature, not only was there better discrimination, but also a significant enlargement of the radiation-induced ESR signal. This signal enhancement is shown in Fig. 1 for the bone fragments (c).

To ensure that the radiation-induced ESR-signal (used for dating) had been stable for at least some 10^6 yr, annealing experiments were carried out. The initial disappearance of the ESR signal between $200\,^{\circ}$ C and $250\,^{\circ}$ C indicates a correlation with the $230\,^{\circ}$ C TL glow peak of natural calcite. This TL signal, which shifts up to $\sim\!275\,^{\circ}$ C when using a fast heating rate, has already been studied by Wintle¹⁹. Isothermal annealing experiments performed on ESR active defects chosen for dating

resulted in exponential signal decays with time constants τ according to an Arrhenius law $\tau = \tau_0 \exp(E_a/kT)$ with a pre-exponential $\tau_0 = 3.8 \times 10^{-14} \, \mathrm{s}$ and a trap depth $E_a = 1.65 \pm 0.1 \, \mathrm{eV}$. This allows us to deduce mean defect annealing times of $\tau = 9 \times 10^7 \, \mathrm{yr}$ and $3 \times 10^8 \, \mathrm{yr}$ for storage temperatures of 15 °C and 10 °C, respectively. These data are in good agreement with the mean lives given by Wintle for TL-dating¹⁹. Thus speleothem dating should be possible using ESR techniques up to a few million years without significant corrections for annealing, particularly as no anomalous fading is observed in the TL of calcite¹².

The heights of the radiation-induced ESR signals were recorded as well as one of the six absorption lines of Mn^{2+} , which are present in practically all ESR spectra of natural calcites. It has been suggested that these lines be used instead of sample weight for the calibration of the radiation-induced ESR-signals. Where possible, we applied both methods of calibration to evaluate the γ -equivalent archaeological doses (EDs).

In the same way the γ -equivalent archaeological doses (EDs) were determined for the other four samples (b)–(e). Results are listed in Table 3.

To obtain the formation ages in years, the EDs are divided by the corresponding radiation doses per year. To determine these annual doses requires that for each sample (see Table 2): (1) the U, Th, K and Rb contents have to be analysed; (2) posssible disequilibria in the natural decay series have to be considered; (3) the efficiency of α -radiation (relative to an identical γ -dose) with regard to the radiation-induced ESR signal has to be determined; (4) the external γ -dose rates at the original sites of the samples must be measured.

U-contents were established by fission-track analysis, using NBS reference glass standard SRM 614. Th, K and Rb contents were determined by INAA and K was independently measured by flame photometry.

An α -spectrometric determination of the $^{230}\text{Th}/^{234}\text{U}$ -disequilibria was not possible for the most useful samples (a)-(d) (directly related to the skull) because of the small amounts and U-content (see Table 2). U-series dating of the massive base travertine (e) yielded an age of $\geq 300,000\,\text{yr}$. The growth of ^{230}Th (which is initially absent in speleothem) and its short-lived daughter nuclides (which are high-energy emitters) towards equilibrium results in a continuously increasing annual dose. Hence, the average annual dose was calculated iteratively with an equation derived by Wintle⁸. ^{222}Rn losses are taken to be negligible for all samples.

For ESR-dating of calcites, there have been no data on the efficiency of an α -radiation dose (relative to a β - or γ -dose) for the generation of unpaired, ESR-active electrons. We thus carried out this calibration on the calcite encrustation of the skull (a) by means of a standardized ²⁴¹Am α -source. The α -efficiency determined for sample (a) was $30 \pm 6\%$ and this value was also used for sample (b) in the same growth horizon.

The external γ-doses were measured by CaSO₄: Dy TL-dosimeters (Harshaw TLD control 4378-32) (ref. 5). Dose rates

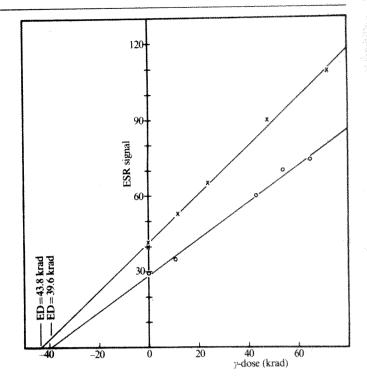

Fig. 2 Determination of the archaeological doses equivalent to ⁶⁰Co γ-irradiation (EDs) of the calcite encrustation (a) of the Petralona hominid skull from two sets of samples. ×, 150 K, 70 mg, calibration by Mn²⁺-signals; ○, 300 K, 150 mg, calibration by weight.

in Petralona Cave varied between 30 mrad yr⁻¹ in some 20-30cm deep boreholes in pure calcite floors and up to ~200 mrad in clay-rich areas. At the site of discovery of the skull an external dose rate of 190 ± 20 mrad yr 1 was recorded on the surface of the travertine floor. The 1 mm polyethylene walls of the dosimeters containing the CaSO₄: Dy partly absorb lowenergy y-rays and thus do not allow total y-dose determinations. In addition, α - and β -radiation from airborne radionuclides (for example, radon and daughter products), which are not recorded by the CaSO₄: Dy monitors, might have also affected the top layers. Hence, for the top layers (a) and (b) the given total dose-rate values may even be underestimated. The external dose rate 3-4 mm beneath the surface (as for samples (c) and (d)) was estimated to be 170 mrad yr⁻¹ because of shielding which was confirmed by laboratory experiments. At various locations, 5-10 cm deep in the travertine floor dose rates varied between 70 and 110 mrad yr⁻¹. Thus a value of 90 ± 20 mrad vr⁻¹ was taken for sample (e).

Although it cannot be proved for any ESR- or TL-dating, the external dose rate is commonly assumed to have remained

	Table 2 Dose rates	per year for the investig	gated samples (a)-(e)		
	(a)	(b)	(c)	(d)	(e)
U-content (p.p.m.)	0.066	0.119	0.418	0.261	0.231
Mean* annual dose (mrad yr 1)	5.0 ± 0.4	9.0 ± 1.4	39.3 ± 16.0	24.5 ± 10.0	35.5 ± 14.5
Th-content† (p.p.m.)	1.84	1.39	0.3	≤ 0.1	≤ 0.1
Annual dose (mrad yr ⁻¹)	14.70	11.1	2.4	≤ 0.8	≤0.8
K-content (p.p.m.)	87	377	139	15	≤ 10
Annual dose (mrad yr ⁻¹)	0.9	4.0	1.2	0.1	≤ 0.1
F intermed done note (mand us-1)	Σ 21 ± 1	Σ 24 ± 1	Σ43±16	$\Sigma.25\pm10$	Σ 36 ± 15
Σ = internal dose rate (mrad yr ⁻¹) External dose rate (mrad yr ⁻¹)	190±20	190±20	170 ± 20	170 ± 20	90±20
Total dose rate (mrad yr ⁻¹)	211 ± 21	214 ± 21	213 ± 36	195 ± 30	126 ± 35

Internal dose rates are calculated from the U-, Th- and K-contents on the basis of the tables of Bell^{21,22}. Dose rate contribution by $Rb \le 0.2$ mrad yr⁻¹ throughout.

*The mean annual dose contributions by U-series nuclides take into account ²³⁴U/²³⁸U- and ²³⁰Th/²³⁴U-disequilibria of ~1.1 and ~0.85, respectively, for samples (a)-(d), according to an age of ~20,000 yr. Secular equilibrium was determined for sample (e) by α -spectrometry. The α -efficiency of $30 \pm 6\%$ evaluated for sample (a) was also used for (b) of the same growth horizon. For samples (c), (d), and (e) the total range of α -efficiencies of 20% to 60% was applied, which have been evaluated in TL-dating of various stalagmites by Wintle⁸ and Bangert (personal communication).

tα-contributions to dose rates are neglected for Th-series, because the bulk of Th is in detrital aggregates (for example, in clay particles).

Table 3 Archaeological y-equivalent doses (EDs), annual doses and ESR age date evaluated for the bone fragments from the Petralona hominid cranium (c) and interrelated calcite strata (a), (b), (d) and (e)

Sample	ED* (ESR) (×10³ rad)	Annual dose (mrad yr ⁻¹)	ESR age (kyr)
(a)	$41.7^{+} \pm 4.2$	211 ± 21	198 ± 40
(b)	$41.8^{\dagger} \pm 4.2$	214 ± 21	195 ± 40
(c)	27.1 ± 2.7	213 ± 36	127 ± 35
(d)	38.6 ± 3.9	195 ± 30	198 ± 50
(e)	$81.7^{+} \pm 12.3$	126 ± 35	\sim 650 ± 280

^{*}Temperature of ESR-measurements is 150 K; linear regression coefficients of ESR growth curves ≥0.99 throughout.

constant since the time of speleothem deposition. For the Petralona cranium this is probably true, because the place of discovery is at the head of a 'dead-end' branch of the cave², where there will be hardly any air movement.

The y-dose rates monitored in Petralona cave by a portable NaI-scintillometer yielded smaller variations in the annual γ -doses (57-91 mrad yr⁻¹) (ref. 20) than those recorded by CaSO₄: Dy-monitors (~30-200 mrad yr⁻¹) (U. Bangert, personal communication). This is due to a higher spatial resolution of the CaSO₄: Dy-dosimeters in recording the γ -dose rates which generally show considerable variations (on a centimetre scale) vertical to the speleothem growth horizons.

From the total dose rates given in Table 2, we deduce absolute ages from the y-equivalent archaeological doses (EDs) (see Table 3).

The ESR-ages of samples (a)-(d) are concordant within their limits of errors and sample (e), which is obviously much older, is not related to the hominid skull. The lower age of the bone fragments (c) compared with (a), (b) and (d) may be due to a partial recrystallization of the apatite crystral lattice of the bone.

Our ESR ages in Table 3 consistently indicate an age of ~200,000 yr for the Petralona cranium. Taking into account the uncertainties of location, the technical difficulties and the controversial interpretations of the cranium, this result may clarify the phylogenetical position of the Petralona hominid, which lies between 160,000 and 240,000 yr BP.

We thank Professor H. Alexander for the use of the ESRspectrometer, and Professor Ch. Schneider and R. Gey for 60 Co- γ -irradiations, U. Bangert for help in evaluating external dose rates, M. Meyer and Dr K. H. Stoch for assistance in trace element analysis, M. Fuchs for technical assistance, especially in fission-track analysis, A. Haidmann and Professor G. Wagner, Heidelberg, for α -irradiations and the Reaktorbetriebsgruppe KFA Jülich for neutron irradiations. The Deutsche Forschungsgemeinschaft is acknowledged for providing equipment. G.J.H. thanks the Bundesministerium für Forschung und Technologie (BMFT) for a research grant.

Isotopic evidence for prehistoric subsistence change at Parmana, Venezuela

Nikolaas J. van der Merwe*, Anna Curtenius Roosevelt† & J. C. Vogel‡

- * Department of Archaeology, University of Cape Town, Rondebosch 7700, South Africa
- † Museum of the American Indian, Heye Foundation New York, New York 10032, USA
- ‡ National Physical Research Laboratory, PO Box 395, Pretoria 0001. South Africa

Recent archaeological results from Parmana, Venezuela, suggest that maize became a staple along the Orinoco River between about 800 BC and AD 400, contrary to prevailing views that maize was not important in prehistoric Amazonia. In maize, carbon dioxide is initially fixed as a C4 carboxylic acid, rather than as phosphoglyceric acid as in C₃ plants. The organic carbon constituents of C₄ plants have a different ¹³C/¹²C ratio from C₃ plants, and this difference is transmitted to animals dependent on maize as a major carbon source. Thus, the 13C/12C ratio of animal remains is a reflection of their diet. Stable carbon isotope measurements on human skeletons from Parmana reported here show that a dramatic shift in the prehistoric diet from dependence on C₃ plants to C₄ plants (which include maize) did take place.

Students of Greater Amazonian cultural development commonly assume that the 'tropical forest' system was the major subsistence system of prehistoric times. In this system most calories are provided by cultivated manioc (that is, cassava) and most protein by hunting and fishing. In the Amazonian forests, where soils are poor and game scarce, tropical forest culture is associated with small, autonomous villages. The development of large, populous chiefdoms in the Amazon and Orinoco mainstreams in late prehistoric times is usually attributed to the higher productivity of the floodplains for tropical forest subsistence1

An alternative argument holds that manioc cultivation and animal capture could not have supported dense populations in floodplains and that larger populations were based on the cultivation of seed crops, particularly maize⁴. Although maize is a minor crop in present Amazonian tropical forest societies, several ethnohistoric accounts⁵⁻⁸ describe it as an important staple in floodplain subsistence. Recent archaeological fieldwork in the Parmana area of the Orinoco basin, Venezuela, suggests that maize may have replaced manioc as the major staple along the Orinoco River during the Corozal phase, between about 800 BC and AD 400, and that the population increased 15-fold during this period.

To assess the archaeological and isotopic evidence for a change in prehistoric diet it is necessary to know the potential human food sources in the Parmana ecosystem, their carbon isotope ratios, and the potential productive capacity of the local tropical forest system as compared with one based on seed crop cultivation. The plants relevant to the discussion are all C₃ or C₄ plants, which have markedly different 13C contents9-11. Cumulative assessments of ¹³C/¹²C ratios in plant foliage, expressed as per mil (%) deviations in 13 C (δ^{13} C) from the Chicago PDB standard 12 , yield mean values of -26.5% for C_3 and -12.5% for C₄ plants, with no overlap between their ranges of values¹³⁻¹⁵ When animals and humans eat plants, these characteristic isotope ratios are registered in their tissues¹⁶, with further fractionation occurring during tissue formation^{17,18}. A fractionation value of +5.1% in human bone collagen, established for prehistoric hunter-gatherers in the North American woodlands 19, is used here for calculations.

Maize (Zea mays) is a C_4 plant. A suitable average $\delta^{13}C$ value for maize kernels based on multiple measurements is not avail-

Mean value of 2 EDs (calibration by weight and Mn²⁺ signals, respectively).

Table 1 δ^{13} C values of some manioc (Manihot esculenta) root products

Laboratory no.	Sample description	δ ¹³ C (%)
UCT-480	Manioc cake purchased in New York City; probable origin the Dominican Republic	-25.6
UCT-481 UCT-483	Same as UCT-480, another example Manioc root, Nkhata Bay, Malawi	-26.0 -25.0

Precision of δ^{13} C is $\pm 0.1\%$.

able, so the average value for C₄ foliage (-12.5%) will be used here. Manioc (Manihot esculenta) is a C₃ plant, as shown by the δ^{13} C values in Table 1. The average for three samples from the Dominican Republic and Malawi is -25.5%, near the C₃ plant average. The samples were presumably cultivated in open fields, however, where the air is well mixed and the CO_2 has the $\delta^{13}C$ value of atmospheric CO₂ at -7%. In dense forests, restricted air circulation and CO2 from rotting leaf litter combine to deplete the 13C content of CO2 available for photosynthesis20. In the Amazonian rain forest, this canopy effect results in leaves of the upper canopy having δ^{13} C values of about -30%, while the undergrowth averages about -35% (ref. 21). The severity of the canopy effect can be expected to vary with forest density. Thus, the effect would be slightly less marked in tropical gallery forests, and less marked still in small forest clearings like swidden fields. No measurements are available for these situations, but it can be assumed that forest plants will have δ^{13} C values more negative than the C₃ plant average of -26.5%.

There are two major components to the Parmana ecosystem-the terrestrial habitats of gallery forest and savannah, and the seasonally fluctuating aquatic habitats of river, stream and lagoon (for detailed refs see ref. 4). Significant human food sources in the natural environment include fauna, a few tree and shrub products, and root plants. Plant material in the ecosystem is predominantly C₃ and forest derived, with the exception of floating meadows, which are C₃ but grow in the open, and savannahs, which have some C4 grasses. The terrestrial fauna include a few grazers which may eat C4 grasses, but are small in biomass and of relatively slow turnover. The aquatic fauna, especially the fish, make up the only substantial intensifiable human food source; they feed on forest-derived plant detritus. Thus, most carbon available to humans from wild sources is derived from C₃ plants and is strongly ¹³C depleted; only a miniscule proportion of the carbon could come from C₄ plants.

The archaeological sequence consists of three ceramic traditions: La Gruta, Corozal and Camoruco^{4,22-26}. Excavations by Roosevelt in 1974 and 1975 provided information on prehistoric subsistence and population⁴. For La Gruta (2100-800 BC), tropical forest subsistence is indicated by ceramic griddles, small stone chips possibly from manioc graters, projectile points and poorly preserved faunal remains. Excavation produced carbonized plants apparently of wild species only (S.G. Stephens and H. Pinkley, personal communication). Population of the 500 km² area was small throughout the period, estimated at 120 or 0.24 per km² (based on a refuse area of 1.5 ha and comparison with ethnographic settlements). The subsistence of Corozal (~800 BC-AD 400) is characterized by the introduction of maize and transition to intensive maize cultivation, with continuation of tropical forest subsistence. Carbonized maize appears for the first time early in the period, becoming common by its end. Possible domestic legumes, as yet unidentified, occur in small quantities throughout Corozal, and possible maize-grinding tools appear. Estimated population for early Corozal is 560 or 1.1 per km² and 1,750 or 3.5 per km² for late Corozal (based on refuse areas of 7.5 and 23.3 ha, respectively). The Camoruco period (AD 400-1500) is characterized by intensive maize cultivation, with manioc cultivation and hunting and fishing probably making a small contribution to calories and protein. Maize remains were abundant, and Canavalia, a tropical bean, was identified (L. Kaplan, personal communication). During this period population stabilized at about 1,800 or 3.6 per km², increasing to about 2,500 or 5 per km² between AD 1100 and 1500 (based on refuse areas of 24.1 and 34 ha, respectively).

The remains suggest a shift during Corozal from tropical forest subsistence, based on manioc, fish and game, to a system based primarily on maize, associated with a sizeable population increase. Maize is conclusively identified, based on carbonized plant remains (W. Galinat, personal communication), but identification of manioc is not conclusive, being based on presumed food-processing tools that could have been used for other foods²⁷. Manioc's presence will be unproven until direct botanical evidence can be found. Moreover, the archaeological finds do not establish the proportion of maize in the diet, due to poor preservation of other foods, especially manioc.

A shift from forest-based subsistence to a diet based on maize should produce a substantial change in the 13 C/ 12 C ratios of human tissues and should be detectable in bone collagen. Given a food web based primarily on plant material from the forest (δ^{13} C more negative than -26.5%) and enrichment in 13 C of 5.1% during collagen formation, human bone collagen should have a δ^{13} C value more negative than -21.4%. A hypothetical diet based entirely on maize or other C₄ plants (such as sorghum and millet) should yield bone collagen with a δ^{13} C value of -7.4%; mixed diets should produce intermediate values.

Stable carbon isotope measurements were made on the five human skeletons recovered from the Corozal site (Table 2); two specimens dated to the inception of Corozal (~800 BC) and three to the Corozal/Camoruco interface (~AD 400). Collagen was extracted from the postcranial remains and converted to CO2 in the Archaeometry Laboratory, University of Cape Town. The procedure involved slow decalcification in 2% HCl, washing in distilled water, vacuum drying and combustion. The bones were badly decomposed by the acid tropical soil, their appearance chalk-white and friable. All the postcranial remains of the child burial (UCT-267) had to be used to obtain the required 0.1 g of dried collagen. Mass spectrometric measurements of the ¹³C/¹²C ratios were made at the Pretoria Radiocarbon Laboratory and related to the Chicago PDB standard through a secondary standard. The results show a substantial isotopic difference between the early and late Corozal skeletons, the two early skeletons having an average δ^{13} C value of -26.0%, and the late group averaging -10.3%; the individual values in each group are closely similar, presumably the result of stable subsistence systems.

The average δ^{13} C values of early and late Corozal diets can be calculated by subtracting the collagen enrichment value of 5.1% from the results in Table 2. The early Corozal diet averaged -31.1%, considerably more negative than the C_3 plant average.

Table 2 δ¹³C values for collagen from human skeletons excavated at Corozal in the Parmana area

Laboratory no.	Provenence	δ ¹³ C (%)
	Late Corozal, ~AD 400	
UCT-259	Skeleton 2 (adult), Exc. 3, level 18- 22, prov. 543	-9.7
UCT-258	Skeleton 3 (adult), Exc. 3, level 18- 22, prov. 544	-10.5
UCT-286	Skeleton 4 (adult), Exc. 3, level 18- 22, prov. 544	-10.8
	Average $(n=3)$	-10.3
	Early Corozal, ~800 BC	
UCT-260	Adult skeleton, centre burial, Exc. 2, level 16-17, prov. 293	-26.1
UCT-287	Child's skeleton, Exc. 2, level 18, prov. 545	-25.8
	Average $(n=2)$	-26.0

Early Corozal skeletons are associated archaeologically with a tropical forest subsistence system (probably manioc, fish and game), Late Corozal skeletons with maize, legumes and probably less manioc and animal food. Precision of $\delta^{13}\mathrm{C}$ is $\sim 0.1\%$.

This result could only have been achieved through a food web which was based primarily on forest-derived plant material, probably to the near exclusion of anything else. Local fauna and manioc raised in the forest would produce such a result, although we cannot prove that manioc was involved. By contrast, the late Corozal diet had an average δ^{13} C value of -15.4%, heavily dominated by C₄ plants. The most likely explanation for this change is the introduction of maize cultivation. No other C4 staple crops are known for the area, nor can a massive increase in the human diet of animals raised on C4 plants be invoked to explain the results, as the faunal remains are primarily of fish (E. Wing, A. Garson and E. Simons, personal communication). If one adopts the explanation that maize cultivation was involved, the proportion of maize in the diet can be calculated. This yields a range of possible results, depending on the food web constructed and the δ^{13} C values used. If the diet consisted entirely of seed crops raised on the floodplain, where normal atmospheric CO2 was available for photosynthesis, it needed to include 80% maize and 20% legumes (δ^{13} C = -26.5%) to achieve the observed results. If some forest-derived plants or animals were included (average δ^{13} C value -31.1%), the maize component needed to be slightly more. Populations depending on maize components >80% are common in the modern Third World²⁸

We conclude that the prehistoric peoples of Parmana maintained a forest-derived subsistence system, probably based mainly on manioc calories and animal protein, until about 800 BC or a little later. By ~AD 400 their diet had changed dramatically to include a maize component of perhaps 80% or more. This change allowed for a 15-fold increase in population, which then stabilized at the higher level. These conclusions help to explain how large concentrations of people and complex societies could have developed in Amazonia.

We thank Irving Rouse for suggesting our collaboration, and A. Darroch, E. Lursen and R. Rawlinson for technical assistance. The laboratory analysis was supported by the University of Cape Town's research committee and the CSIR of South Africa. The archaeological work was supported by the Wenner-Gren Foundation, Social Science Research Council, Yale University and Museum of the American Indian.

Relationship of aardvark to elephants, hyraxes and sea cows from α -crystallin sequences

Wilfried W. de Jong*, Anneke Zweers* & Morris Goodman†

*Department of Biochemistry, University of Nijmegen, 6500 HB Nijmegen, The Netherlands †Department of Anatomy, Wayne State University, School of Medicine, Detroit, Michigan 48201, USA

One of the great enigmas of mammalian phylogeny is the genealogical relationship of the aardvark (Orycteropus afer), the only living representative of the order Tubulidentata. Although now generally grouped close to the ungulates and paenungulates. 4, and thought to be derived from a common , and thought to be derived from a common condylarthran stock⁵⁻⁷, it still holds an isolated position among eutherian mammals. The evidence of the evolutionary relationships of the aardvark may be obscured at the morphological and anatomical level by the pronounced adaptations to its ant-eating and burrowing habits, and may be better preserved in its protein molecules, as direct copies of the genetic material. We have therefore now studied the amino acid sequence of the eve lens protein lpha -crystallin A of the aardvark, and compared it with the corresponding sequences from species representing 15 mammalian orders. Unique similarities were observed among the α -crystallin A sequences of aardvark and the paenungulates manatee, hyrax and elephant, suggesting that the closest relatives of the Tubulidentata are found in the paenungulate orders Sirenia (sea cows), Hydracoidea (hydraxes) and Proboscidea (elephants). Moreover, these orders do not seem to be derived from a common stem group with the ungulates, but might well be one of the first offshoots of the placental mammalian line.

α-Crystallin is a high molecular weight protein aggregate, essentially composed of two types of polypeptide chain, α A and αB, each about 175 residues long8. α-Crystallin occurs in considerable quantities in the eye lenses of all vertebrates9, and thus can readily be isolated and analysed. Sequence analysis of the α -crystallin A chain has previously been used to study phylogenetic relationships between 11 mammalian orders¹¹ The results mostly agreed with prevailing opinions about mammalian phylogeny, and prompted the investigation of the αA chains from species representing orders of more disputed affinity, like Edentata (sloths and anteaters)11, Pholidota

Phylogenetically informative positions in aardvark, manatee and other published mammalian α -crystallin A sequences^{10,11} Table 1

Only those positions are shown at which substitutions have occurred in at least two of the investigated species. Full species names can be found in refs 10 and 11. Vertical lines indicate where residues are identical to the topmost sequence. Positions which determine the paenungulate branching pattern as shown in Fig. 2 are marked by an asterisk. The one-letter notation for amino acids is: A, Ala; C, Cys; D, Asp; E, Glu; F, Phe; G, Gly; H, His; I, Ile; K, Lys; L, Leu; M, Met; N, Asn; P, Pro; Q, Gln; R, Arg; S, Ser; T, Thr; V, Val; Y, Tyr; (-) indicates a deletion.

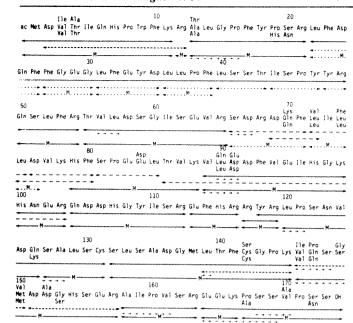

Fig. 1 Summary of sequence analysis of aardvark and manatee α -crystallin A chains. The central line represents the proposed sequence of aardvark α A. Residues which are different in the bovine α A chain¹⁸ are shown above the aardvark sequence and those residues in which the manatee α A chain differs from the bovine chain are given below the aardvark sequence. Positions 40-49 and 77-78 of the manatee sequence could not be determined, and a substitution Ser - Asn has occurred either at position 172 or 173. From three aardvark lenses and six manatee lenses, 36 mg and 12.5 mg, respectively, of α A chains could be isolated. The isolation and sequence analysis of the α A chains followed previously detailed methods¹⁹. The procedure is largely based on amino acid analyses of small peptides, which are compared with corresponding ones of the completely sequenced bovine αA chain¹⁸. When amino acid compositions of homologous peptides are found to be the same, it is assumed that their sequences are also. Peptides which differ in composition from corresponding bovine ones are, if possible, subjected to dansyl-Edman degradation to localize the positions of substitutions. The inaccuracy in the sequences so deduced is very small²⁰. This figure shows by different underlinings the peptides from which satisfactory amino acid analyses could be obtained. Peptides and residues within these peptides are mainly ordered by homology with the known bovine sequence18. The positions of a number of residues were determined by dansyl-Edman degradation $(\rightarrow \rightarrow)$. Aardvark αA chain: Tryptic peptides $(\leftarrow \rightarrow)$ were isolated by peptide mapping and gel filtration¹⁹. The large tryptic peptide 22-49 was further digested with thermolysin and the resulting small peptides (←···→) isolated and analysed. From a tryptic digest of citraconylated cyanogen bromide fragment (residues 2-138) was isolated peptide 2-12 --→) and a large peptide containing residues 66-104. The latter peptide was decitraconylated and digested with chymotrypsin (-which resolved the sequence 66-88. Cyanogen bromide fragments corresponding to residues 139-150 and 151-173 were digested with trypsin. The resulting peptides $(\leftarrow ---\rightarrow)$ covered the region 146-157. Manatee α A chain: Soluble tryptic peptides (\leftarrow M \rightarrow) were isolated by peptide mapping. A thermolytic digest of the water-insoluble tryptic core yielded peptides (← · · · M · · · →) which resolved residues 22-39 and the important region 66-76

(pangolins)¹¹ and now the Tubulidentata. Although the relationship of Sirenia to the other paenungulates has not been questioned¹⁻⁷, we, nevertheless, report here the α A sequence of the Brazilian manatee (*Trichechus inunguis*) because it increases the body of relevant data on which to base our phylogenetic inferences.

 α -Crystallin was isolated from three aardvark lenses and six manatee lenses, and the sequences of the αA chains were analysed as shown in Fig. 1. Comparison of the proposed aardvark and manatee αA sequences with the data set of other αA chains (Table 1) clearly reveals that both sequences share three or four apparently derived substitutions with hyrax and elephant: $70 \cdot \text{Lys} \rightarrow \text{Gln}$, $72 \cdot \text{Val} \rightarrow \text{Leu}$ (not present in elephant), $74 \cdot \text{Phe} \rightarrow \text{Leu}$ (also in the edentate Tamandua) and $142 \cdot \text{Ser} \rightarrow \text{Cys}$ (also in man). No substitutions are uniquely shared with any other particular eutherian order. The aardvark and manatee αA chains each have in addition a relatively large number of unique substitutions: four in the aardvark (84 Glu, 149 Ser, 152 Asp, 170 Val) and five in the manatee (19 His, 20 Asn, 126 Lys, 167 Ala, 172 or 173 Asn).

To assess the sequence relationships of the aardvark and manatee a A chains more objectively and quantitatively, trees were constructed for the available a A sequences, using a maximum parsimony approach 12,13. The fewest possible number of nucleotide replacements (NRs) to arrange the 23 mammalian sequences, and the chicken and frog (Rana esculenta) sequences¹⁰ as outgroups, in an ancestral branching order, was found to be 133. Several equally parsimonious trees could be constructed which, however, all agreed in the positioning of the aardvark and the place of the paenungulates in relation to the other mammalian orders (Fig. 2). These most parsimonious trees clearly suggest a monophyletic origin of aardvark and paenungulates. Indeed, to separate the aardvark from the paenungulate branch, and place it at the base of the edentate line or as a separate branch next to edentates and paenungulates. costs an additional 4 NRs. All other positions are even less parsimonious. The most parsimonious solutions depict the elephant as the first offshoot of the paenungulates, due to the substitution 72 Val → Leu in hyrax, manatee and aardvark (Fig. 2). There is good morphological evidence to place elephant and manatee closest together¹⁻⁶. This would require one additional substitution, most probably a back substitution 72 Leu → Val in the elephant line. Faster evolving proteins, like myoglobin and haemoglobin, might provide better evidence on the phylogenetic relationships among the living paenungulate orders.

The suggestion that the Tubulidentata should be included in a monophyletic superorder Paenungulata is supported by some independent osteological and immunological findings¹⁴. Significant morphological resemblances of aardvark to hyraxes and elephants has already been noted¹⁵. Interestingly too, Tubulidentata, Hyracoidea, Sirenia and Proboscidea all seem to be indigenous African orders, which came into existence during the early Tertiary isolation of the continent⁵⁻⁷.

In agreement with our previous results ^{10,11}, the Edentata and Paenungulata are consistently placed as the oldest offshoots from the main eutherian line (Fig. 2). This is mainly due to the absence in these orders of the substitutions 91 Asp → Glu and 153 Ser → Gly, shared by almost all other eutherian orders (Table 1). Such an early divergence of the edentates is in agreement with recent opinions about their phylogenetic position^{3,16}. More surprising is the ancient separation of a paenungulate branch, far from the ungulates. It would in fact cost at least 5 additional NRs to place the paenungulates and aardvark in the ungulate—cetacean region of the tree. Although the paenungulates are usually grouped among the ungulate orders, Romer⁵ states that it is "far from certain that they form a single natural group".

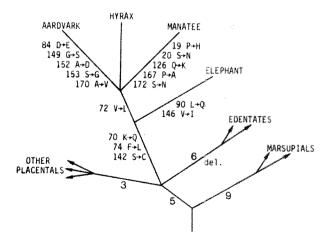

Fig. 2 The aardvark-paenungulate region of the most parsimonious phylogenetic trees constructed on the basis of α -crystallin A sequences from 23 mammalian species (Table 1), and from chicken and frog as outgroups. Several equally parsimonious trees are possible, which differ in the precise branching pattern of the other placental orders. The inferred amino acid substitutions in the aardvark and paenungulate lines are indicated. Numbers of nucleotide replacements are given in neighbouring branches. A deletion of three residues occurs in the edentate α A chains.

No other protein sequence data are available from aardvark, hyrax and manatee to corroborate our proposals. However, the sequences of elephant β -haemoglobin, myoglobin and fibrinopeptides are known and also fail to group the Proboscidea with the ungulates 17

We thank Dr P. J. H. van Bree, the 'Artis' Zoo, and Dr J. Shoshani for aardvark lenses, Dr R. Best for manatee lenses, Marlies Versteeg for amino acid analyses, and Dr M. C. McKenna for helpful discussions. This work was supported in part by the Netherlands Foundation for Chemical Research (SON) with financial aid from the Netherlands Organization for Pure Research (ZWO), and by NSF grant DEB 7717182 to

Experience required for pheromone recognition by the apple maggot fly

Bernard D. Roitberg & Ronald J. Prokopy

Department of Entomology, University of Massachusetts, Amherst, Massachusetts 01003, USA

Remarkable progress has been made during the past 20 yr in the identification of chemical components and receptor sites of pheromones of various insects. However, our understanding of the physiological and ecological parameters which affect the response of individual insects to pheromones remains rather limited. Here we report that in apple maggot fly, Rhagoletis pomonella, females require experience with oviposition-deterring pheromone (ODP) before they are able to discriminate between ODP-marked and unmarked host fruit. This seems to be the first conclusive evidence in an insect that pheromone recognition may depend on previous contact with the particular

After egg laying in the fruit flesh, a R. pomonella female deposits ODP by dragging its ovipositor on the fruit surface One bout of dragging on a hawthorn (Crataegus sp.) fruit of ~5 mm diameter deters the same or other females from ovipositing in that fruit in the field, although the degree of deterrence is reduced in the laboratory. Prokopy suggested that the ODP elicits uniform egg distribution among larval food resources, a character which has high survival value in so far as only a limited number of larvae can mature in a single fruit.

We found that recently matured females deprived of host fruit until testing did not discriminate between ODP-marked and

unmarked hosts. In contrast, females that were allowed access to ODP-marked host fruit 1 day before testing generally rejected ODP-marked fruit (Table 1, expt 1). To determine whether these results stemmed from a difference between females in oviposition deprivation or to a difference in previous contact with ODP, we placed newly matured wild flies singly in cages and treated each fly in one of two ways.

In treatment A, each fly was presented with and allowed to oviposit in one clean (no ODP), uninfested hawthorn fruit. Immediately after oviposition, the fly was transferred using a small triangular piece of clean filter paper to a clean uninfested apple, where it was allowed to deposit ODP. We directed the fly's course of dragging on this much larger fruit so that it never contacted its own pheromone trail with its pheromone receptors (tarsal D-hairs)2.3. We repeated this procedure twice more at 45-min intervals on day 1. On day 2, we again repeated the procedure twice. Forty-five minutes after the second oviposition, we presented the fly with a 5-mm diameter hawthorn fruit marked with ODP from two dragging bouts by other females.

Treatment B flies were also allowed to oviposit in three hawthorn fruits and drag on three apples on day 1. However, the second and third hawthorn fruits offered were marked with ODP from three previous (~1 h earlier) dragging bouts. If the flies rejected the marked fruit, they were presented with clean fruit for oviposition. The procedure followed on day 2 was the same as for treatment A flies.

Treatment B (experienced) flies generally rejected ODPmarked fruit and accepted clean ones. Treatment A (naive) flies readily accepted ODP-marked fruit (Table 1, expt 2a). In addition, significantly more treatment A than treatment B flies rejected clean fruit presented to them after their rejection of a marked fruit. This experiment was repeated, with similar though less dramatic results (Table 1, expt 2b).

Prokopy4 reported that barometric pressure may affect the level of activity and ODP discrimination ability of apple maggot flies. In expt 2a and b we found that more flies completed the experimental protocol on days with moderate or high barometric pressure (≥29.7 mbar). When we reexamined data for expt 2b including only data from days in which we were able to test to completion at least four naive and four experienced flies, 71% (n = 14) of the naive flies accepted ODP-marked fruit compared with 40% (n = 10) which accepted on days when we were unable to test four naive and four experienced flies.

To determine whether flies could obtain necessary pheromone experience by contacting their own ODP trail while dragging, we repeated the experimental protocol, but did not transfer the flies to apples for dragging. All flies contacted their own trail an average of 4.4 times (per fruit) while dragging. In this case, treatment A flies rejected ODP-marked fruit as readily as did treatment B flies (Table 1, expt 3).

In a final test, we withheld experienced flies from ODP for 96 h (flies were allowed to oviposit and ODP drag, but not contact any ODP, three times on each of the 4 days) and found that they rejected ODP-marked fruit as readily as did recently experienced flies, thus demonstrating the retention of ability to recognize ODP for at least 4 days (Table 1, expt 4). Klomp et al. reported that Trichogramma embryophagum, a hymenopteran parasite of lepidopteran larvae, forgets and must relearn to discriminate between parasitized and non-parasitized hosts. However, they suggested that their results could be explained by the increasing tendency of the wasps to oviposit at increasing time of deprivation from oviposition sites.

Alcock's definition⁶ of 'restricted learning', that is, 'an animal acquires a limited piece of information from the environment that changes the behaviour of the animal in a precise manner', can be applied to the ability to recognize ODP by apple maggot flies. Electrophysiological tests show that the ODP receptors on the tarsi fire the first time they contact ODP (L. Bowdan, V. Dethier and R.J.P., unpublished data). However, our results show that such a message is not translated into a rejection response in naive flies. This mechanism may provide flies with a means of reducing the cost of continually maintaining an unused

Table 1 Response of apple maggot flies to ODP-marked hawthorn fruit before and after experience with ODP

Ex	periment	Treatment	n	% Rejection of ODP-marked fruit*	n	% Rejection of clean fruit after rejection of an ODP-marked fruit
	1	No previous host or ODP experience	17	$17.6 (P \le 0.001)$	5	40.0 (NS)

	4	96-h ODP deprivation No ODP deprivation	16	56.3	9	22.2

^{*} If a fly rejected ODP-marked fruit, we presented it with a clean fruit. If the fly also rejected the clean fruit we disqualified it from this analysis. NS, not significant.

information processing system, because flies may not encounter ODP-marked fruit in conditions of high fruit density, low fly population or when immature. However, once mature flies have oviposited in a single small hawthorn fruit (= native host fruit) they may gain, through tarsal contact with their own ODP trail, the pheromonal experience needed to activate the system.

We are carrying out further experiments to determine why naive apple maggot flies reject clean fruit more often after encountering ODP than do experienced flies.

We suggest that restricted learning of pheromone recognition may be more widespread than is believed. For example, Cammaerts-Tricot7 and Le Moli and Passetti8 suggested, but did not prove, that perception of pheromones by Myrmica and Formica ants, respectively, depends on experience, and Vinson et al.9 demonstrated associative learning of kairomonal ovipositional cues by Bracon mellitor, a parasitic wasp. van Lenteren and Bakker10 first demonstrated that Pseudeucoila bochei, a

hymenopteran parasite of Drosophila larvae, must 'learn' to discriminate against parasitized hosts. Their results strongly suggest that the key component in the learning process is the marking pheromone deposited by P. bochei after oviposition. However, because the parasite marks its hosts internally, van Lenteren and Bakker were unable to demonstrate pheromonal contact. Our study parallels their pioneering work and provides the first unequivocal evidence for pheromone learning in

Inherited abnormalities of colour vision are most commonly attributed to abnormalities of the photosensitive pigments in the cone cells of the retina^{1,2}. Here, we describe direct microspectrophotometric measurements on the eyes of two squirrel monkeys whose colour vision had been shown to differ behaviourally. Our results are consistent with classical explanations of abnormal colour vision.

Some colour-deficient human observers are dichromats, which means that they are able to match any colour with a mixture of two primary lights, whereas the normal, trichromatic observer requires three variables. It is exactly two hundred years since von Gentilly3-5 advanced the most natural explanation of this condition, that the dichromat lacks one of the three types of retinal receptor enjoyed by the normal trichromat. It is also one hundred years since Lord Rayleigh described a different abnormality of colour vision, anomalous trichromacy. Like the normal, the anomalous observer requires three variables in colour matching, but in matching a mixture of red and green to a monochromatic yellow light (the 'Rayleigh match') he needs either more red (protanomalous) or less red (deuteranomalous) than the normal. This has been explained by supposing that the anomalous retina contains three types of photopigment but that the absorbance curve for one of them is displaced along the spectrum from its normal position 1,2,7-11. Despite much work, the exact relationships between the various types of colour vision and retinal photopigments are far from settled. Two recent developments have led to the present report. First, it has been shown that among a population of squirrel monkeys (Saimiri sciureus) there occur clear variations in colour Second, the technique of microspectrophotometry¹⁴⁻²⁰, in which a narrow, monochromatic, measuring beam is passed through isolated photoreceptors, has advanced to a stage where it is possible to characterize the types of receptor within an individual primate retina and thus relate the results to earlier behavioural measurements on the same subject.

The squirrel monkeys examined in the present study were both adult females of the subtype exported through Iquitos, Peru²¹; they were drawn from a larger group trained on colour vision tests in Santa Barbara, California. The behavioural tests 12,13 were all conducted in a forced-choice discrimination apparatus in which the monkeys viewed three circular, transilluminated panels. They were taught to touch one of the three panels which was illuminated differently from the other two, in order to receive a 97-mg banana-flavoured food pellet. Which of

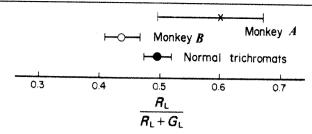

Fig. 1 Rayleigh match results from squirrel monkeys and humans. The match values are expressed as the ratio of the luminance of a red (624 nm) light ($R_{\rm L}$) to the sum of the luminances of the red and green (536 nm) lights ($R_{\rm L}+G_{\rm L}$) needed in a mixture to match an equiluminant yellow (585 nm) light. The solid circles give the average values for 20 normal human trichromats, so categorized by their performances on the Farnsworth–Munsell 100-hue test. The horizontal line shows the total range of matches made by this sample of subjects. The results for the two monkeys were obtained from tests in which they were forced to discriminate between a red/green mixture and a yellow. Across repeated test sessions, 21 different mixture combinations were tested. The large symbols represent the midpoints of the range of mixtures over which they were unable to discriminate various red/green combinations from yellow; the horizontal bars enclose the mixture range over which their discrimination performances were not significantly different from chance (95% confidence level).

the three panels was positive (that is, differently illuminated) varied randomly from trial to trial.

Results from three tests of vision are reported. First, detection thresholds were measured for 540 and 640 nm monochromatic test lights superimposed on achromatic backgrounds (3 cd m⁻²). One animal (A) was 1.27 log units less sensitive to the 640 nm light than to 540 nm, whereas the other (B) was much more sensitive to the long-wavelength light, showing a threshold difference of only 0.36 log units. Sensitivity variations of this magnitude are characteristic of this species¹².

Two further tests specifically examined colour vision. The first was a Rayleigh match assessing the relative proportions of mixed red (625 nm) and green (536 nm) light that the animal was unable to discriminate from a yellow (585 nm) (Fig. 1). Human subjects were tested in the same apparatus and the matches (mean and total range) obtained from 20 normal trichromats are shown in Fig. 1 for comparison. For the monkeys, the symbols represent the midpoints of the range over which they were unable to discriminate the red/green mixture from the yellow and the horizontal bars show the mixture range over which their discrimination was not significantly different from chance. It will be seen that monkey B required somewhat more green light in the mixture than any of the normal human trichromats whereas monkey A required much more red. Note also that the mixture range that could not reliably be discriminated from yellow was very much larger for subject A.

In another experiment we measured, at each of 10 spectral locations, how much the wavelength of a test light had to be shifted along the spectrum for the animal to discriminate a wavelength difference correctly. The abilities of the two monkeys to distinguish wavelengths were very similar for values from $450 \text{ to} \sim 540 \text{ nm}$ (Fig. 2). At longer wavelengths, monkey B continued to show relatively good discrimination, but A's discrimination worsened strikingly.

If we categorize the animals in terms of human vision, then monkey A was a protan; we leave open the question of whether she was an extreme protanomal or a true dichromat. Monkey B requires significantly more green light in the Rayleigh match than the normal human trichromat, and we describe her as deuteranomalous, but she is less aberrant in this regard than the typical human deuteranomalous observer^{1,2}.

The behavioural results were not known to the microspectrophotometrists (J.K.B. and J.D.M.), nor the microspectrophotometric data to G.H.J., until the two sets of results had been handed to an independent third party.

The monkeys were flown to Britain, where microspectrophotometric measurements were made with a modified Liebman microspectrophotometer^{16,22} under computer control. The preparation of tissue was as described for *Macaca fascicularis* by Bowmaker, Dartnall and Mollon¹⁹. Several samples were

taken from each retina. The microspectrophotometer was programmed to step from 700 to 390 nm in 2-nm steps, taking wavelengths with even values, and to return taking the interleaved wavelengths. A total of 34 individual records were obtained from animal A, and 47 from B.

Figure 3 shows for each animal (1) the mean absorbance curve for each class of photoreceptor, excluding short-wave cones, which were too few to provide mean spectra, and (2) the distribution of peak sensitivities for all individual records. From animal A we recorded 2 violet-sensitive receptors (mean λ_{max} = 431.3 nm), 13 rods (mean $\lambda_{\text{max}} = 496.4$ nm, s.d. = 4.69) and 19 green-sensitive receptors (mean $\lambda_{\text{max}} = 535.4 \text{ nm}$, s.d. = 3.45); the longest λ_{max} estimated for any cell of this animal was 542.5 nm. The mean and standard deviation for the P535 receptors closely resemble those for the middle-wavelength receptors of macaques¹⁸⁻¹⁹. Because animal A seems to have only one photopigment in the red-green range, its behavioural sensitivity at 640 nm relative to that at 540 nm should be directly predictable from the microspectrophotometric measurements. From the mean absorbance values at the two wavelengths we estimated log absorptance¹⁹ for an axial beam, assuming an outer segment length of 30 µm and a pigment density of $0.015~\mu\text{m}^{-1}$ and assuming that absorption by the ocular media is identical at 540 and 640 nm. This calculation predicts a difference in log sensitivity of 1.23, very close to the obtained value of 1.27

From monkey B we recorded one short-wave receptor ($\lambda_{\text{max}} = 427 \text{ nm}$), 24 rods (mean $\lambda_{\text{max}} = 501.7 \text{ nm}$, s.d. = 3.58), no receptors in the vicinity of 535 nm and a broad range of receptors with peak sensitivities between 546 and 577 nm. There is no overlap between the long-wavelength receptors from this animal and the P535 receptors from the protan, a highly significant difference (z = 5.63, Mann-Whitney U-test).

The long-wave receptors of animal B, taken as a whole, have a higher standard deviation (8.17 nm) than we should typically expect for a single class of photoreceptor in an individual primate; and prima facie they fall into two groups, with a gap in the distribution at 562 nm (Fig. 3d). The two groups have means of 552.2 nm (n = 16) and 568.2 nm (n = 9). The latter value can be compared with the mean of 567.0 nm obtained for the long-wavelength receptors of Macaca fascicularis. Our confidence in the existence of more than one long-wavelength pigment in this animal is reinforced by the fact that the mean absorbance spectra for the two subgroups (Fig. 3c) show very similar absorbance at short wavelengths and seem to have a constant separation; we should not expect this to be the case if, say, the large variation in λ_{max} arose from variations in optical

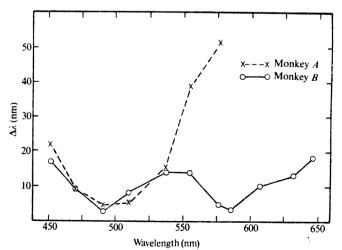

Fig. 2 Wavelength discrimination functions for two squirrel monkeys. The wavelength discrimination values $(\Delta\lambda)$ indicate the magnitude of the wavelength change required at each spectral location to support discrimination between two equiluminant spectral lights at a criterial level of 70% correct. The values are averages for differences in both spectral directions except at 452 nm where the change could only be measured towards the longer wavelengths.

scattering or in the presence of photoproducts at short wavelengths, which would distort the absorbance spectrum.

As in macaques and man^{19,20}, the short-wave receptors seem to be rare in squirrel monkeys. In the case of the rods there is a 5-nm difference between animals in λ_{max} , a difference which is associated with a small difference in absorbance at short wavelengths; we do not know whether the latter difference reflects short-wave contaminants or a true difference in the absorbance spectrum.

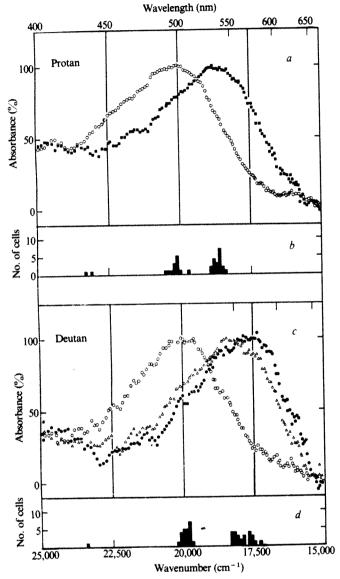

Fig. 3 a, c, Mean absorbance spectra for different classes of photoreceptor in two individual squirrel monkeys. Each datum point corresponds to the average of values obtained at two adjacent wavelengths, one value recorded in the descending scan (see text) and the other recorded in the ascending scan. The absorbance spectra for individual receptors were not normalized before averaging. The mean spectra have been normalized to have a maximum of 100%. b, d, Distribution of values of peak sensitivity of individual receptors from the protan (b) and deutan (d) animals. The bin size is 100 cm⁻¹. With the exception of the three short-wavelength receptors, values of peak sensitivity were derived as follows. The raw absorbance values for individual wavelengths were smoothed using an 11-nm running average The approximate peak of this curve was estimated and each of 50 individual (smoothed) absorbance values on either side of the provisional peak was referred to an appropriate nomogram to estimate the wavenumber of peak sensitivity; this operation amounts to finding where the nomogram must be located on a wavenumber abscissa to yield the absorbance value under consideration. The mean of the many separate estimates for a given cell is the value entered in the histogram. This method resembles that described by Bowmaker et al. 19, except that the smoothing and subsequent analysis are carried out by the computer and more individual estimates are used. For the three short-wavelength records we estimated wavenumber of peak sensitivity directly from the 2-nm averages (see above) in the restricted range 400-475 nm, using the frog green-rod nomogram²².

This first microspectrophotometric study of behaviourally different conspecifics is consistent with classical explanations of colour deficiency and anomaly. Within the limits of our sampling, the severely protan animal lacks entirely the long-wave receptors found in macaques^{18,19}. The deuteranomalous animal lacks the P535 receptors found in the protan but probably has more than one type of receptor in the range 546-577 nm.

This work was supported by NIH grant EY-02052 and MRC grant 979/219/N. We thank Professor H. B. Barlow FRS for holding the two independent sets of data, P. F. Martin and B. E. Reese for experimental assistance in Santa Barbara, and Mr M. W. Smith for veterinary supervision in Cambridge.

Spatial summation and contrast sensitivity of X and Y cells in the lateral geniculate nucleus of the macaque

Robert Shapley, Ehud Kaplan & Robert Soodak

The Rockefeller University, 1230 York Avenue, New York, New York 10021, USA

Study of parallel processing in the visual pathway1 of the cat has revealed several classes of retinal ganglion cells which are physiologically distinct and which project to various locations in 3. Two classes have been studied most extensively: X cells, which sum neural signals linearly over their receptive fields, and Y cells, in which the spatial summation is nonlinear 1.4. In the cat's lateral geniculate nucleus (LGN) cells also can be classified as X or Y, a result of the parallel projection of retinal X and Y inputs to different geniculate neurones 5-9. We report here our study of parallel signal processing in the LGN of the macaque monkey. We find that (1) monkey LGN cells can be classified as X or Y on the basis of spatial summation; (2) X-like cells are found in the four parvocellular and the two magnocellular laminae, whereas Y-like cells are found almost exclusively in the magnocellular laminae; and (3) the cells of the magnocellular laminae have high sensitivity and the parvocellular cells low sensitivity for homochromatic patterns. This implies that in macaque monkeys the magnocellular cells and their cortical projections may be the neural vehicle for contrast vision near threshold. The cells of the parvocellular laminae seem to be primarily concerned with wavelength discrimination and patterns of colour. As the human visual system is similar to that of the macaque in structure and behavioural performance, our findings are probably also applicable to man.

In macaque monkeys, as in man, the LGN is a highly organized, layered nucleus. There are four dorsal layers of small cells (parvocellular) and two ventral layers of large cells (magnocellular). Previous investigators 10-12 concluded that there was a complete segregation of X and Y cells in the monkey's geniculate nucleus, the X cells residing in the parvocellular laminae and the Y cells in the magnocellular laminae. These conclusions depended on identifying X and Y cells by the time course of response to visual stimulation and the latency of response to electrical stimulation of the optic chiasm. Although such characteristics have been used to classify X and Y cells in the cat LGN^{6,7}, a correlation between response time course and linearity of spatial summation has not been established for neurones of the monkey's LGN.

In our experiments we used nine cynomolgus monkeys (Macaca fascicularis) anaesthetized with urethane (20 mg per kg per h) and paralysed with Flaxedil. The activity of single cells was recorded extracellularly using glass micropipettes (tip resistance, $10-30~\mathrm{M}\Omega$). In about half the penetrations the pipettes were filled with a saturated solution of Fast Green dye in Ringer's solution to mark the position of the recording electrode. Electrode tracks were reconstructed from histological sections by using the dye marks and distances traversed along the track. This was important for assigning a given cell to a particular geniculate lamina because laminar boundaries are often irregular and the layer 3-layer 2 boundary, which is the critical parvocellular-magnocellular boundary, is not accompanied by an eye change. Visual stimuli were produced electronically on the face of a CRT¹³ which subtended 10° by 8° in

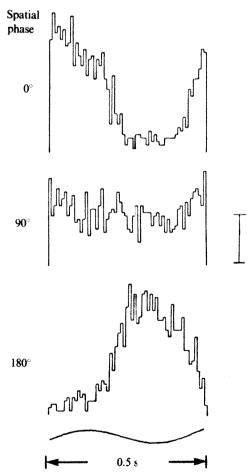

Fig. 1 Response of an X cell from a magnocellular layer at three different positions (spatial phases). The cell was recorded in layer 2 of the macaque's LGN. The stimulus was a sine grating of 1.5 cycle deg⁻¹, 50% contrast, contrast reversed with a sinusoidal time course at 2 Hz as indicated at the bottom of the figure. 0° and 180° were spatial phases at which the stimulus produced maximal responses; 90° was the spatial phase of the null response. The vertical calibration, drawn close to the middle histogram, is 30 impulses per second.

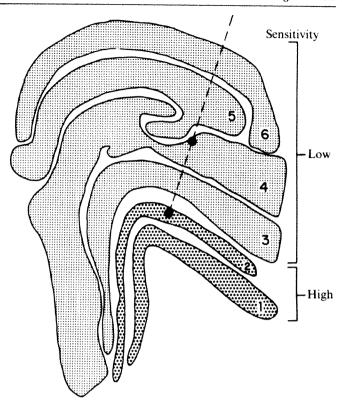

Fig. 2 Contrast sensitivity in the macaque's LGN. This drawing is traced from a single 100-μm thick section of the LGN. The parvocellular laminae are numbered 6, 5, 4 and 3 and the magnocellular laminae 2 and 1. The parvocellular cells all had lower contrast sensitivity than did the X and Y cells of the magnocellular laminae. A reconstructed electrode track is shown; the two dark circles represent green dots left by the electrode at sites where (1) a typical parvocellular X cell of low sensitivity was recorded in layer 4 and (2) a typical magnocellular X cell of high contrast sensitivity (>50) was recorded in layer 2. The latter was the first cell of high contrast sensitivity found on this track.

visual angle. In some experiments a CRT with a P31 (green) phosphor was used, in others a CRT with a P4 (white) phosphor with no difference in results. The mean luminance was 20-60 cd m⁻², in the low photopic range. The pupils were dilated to ~ 6 -mm diameter and the eyes protected with clear plastic contact lenses. In several experiments Wratten colour filters (no. 26, red; no. 61, green; no. 48A, blue) were placed in front of the CRT to check whether linearity of spatial summation depended on the colour of the screen.

Cells were classified as X or Y by means of their response to sine gratings, patterns in which the luminance varied sinusoidally with position in one dimension. The contrast of the gratings was reversed with a sinusoidal time course^{4,8,9}. A cell was called X if it responded to low and high spatial frequency patterns as if it received input from a single linear receptive field mechanism. This means that an X cell would respond to contrast reversal of the grating at the temporal modulation frequency, and its response would exhibit a sinusoidal dependence on the position (or spatial phase) of the grating^{4,8,9}. A cell was called Y if it responded to low spatial frequencies approximately like an X cell, but revealed only nonlinear behaviour at higher spatial frequencies. The nonlinear behaviour looked for, based on our experience with cat Y cells, was frequency doubling of responses to contrast reversal. In monkey Y cells, as in the cat, a frequency-doubled response was present at all positions of the grating. Classification of cells as X or Y did not depend on the colour of the screen in the experiments with Wratten filters. That retinal ganglion cells in the monkey can be classified as X or Y has been previously reported14. Thus, in the monkey, as in the cat, retinal ganglion cells confer their characteristic properties on their geniculate targets.

Cells classified as X by above criterion were found in all laminae of the macaque's LGN. Figure 1 shows the responses of a magnocellular X cell to the stimulus of a 1.5 cycle deg⁻¹ sine grating undergoing contrast reversal with a sinusoidal time course at 2 Hz. Responses at three different positions or spatial phases are shown: at 0° spatial phase there was a maximal response, at 90° no response, and at 180° the response peaked again.

Almost all the parvocellular cells recorded were X cells (225 out of 226 cells recorded and assigned to the parvocellular laminae by histological reconstruction of tracks); only one was a Y cell. Most of the magnocellular cells recorded were also X cells (59 out of 77 cells assigned to the magnocellular layers); the rest were Y cells. Thus, our results show that magnocellular cells do not form a homogeneous class with respect to spatial summation properties. Similar results have been reported in preliminary form elsewhere 15-18.

We next investigated functional differences between parvocellular and magnocellular cells by comparing their contrast sensitivities. Contrast sensitivity was determined as the reciprocal of the contrast required to give a modulated discharge with an amplitude of 5 impulses per second in response to a drifting sine grating. The spatial frequency of the grating was varied from 0 to 10 cycle deg⁻¹, and the peak contrast sensitivity for each cell was determined. The parvocellular cells had much lower peak contrast sensitivity than the magnocellular cells. The parvocellular cells had a peak contrast sensitivity of 10. Both X and Y cells in the magnocellular laminae had a peak contrast sensitivity of approximately 75. The contrast sensitivity of magnocellular cells was high enough that it might account for the behavioural contrast sensitivity of Macaca fascicularis 19. Figure 2 shows that the magnocellular layers are the site of high contrast sensitivity and the parvocellular laminae contain cells which are relatively insensitive to luminance contrast. Our discovery that parvocellular neurones have low contrast sensitivity is consistent with previous evidence that these cells analyse colour 10,12,20,21. Note that peak contrast sensitivity did not show a strong dependence on the colour of the CRT screen in the experiments with Wratten filters.

The contrast sensitivities of cells in the magnocellular laminae of the monkey are comparable with those of cells in the A and A1 laminae of the cat LGN. As the parvocellular X cells were far less sensitive to contrast, the proposed homology between the X cells in the parvocellular laminae of the monkey and X cells in the cat LGN¹⁰⁻¹² is not compelling. A closer homology exists between the X and Y cells of the magnocellular laminae and the X and Y cells of the cat LGN. The parvocellular laminae of the monkey's LGN, and their retinal inputs, seem to form a visual neural pathway which is not present in cats.

Two genes interact to control development of a lymphoid/erythroid hyperplastic disorder of mice

Luisa DeGiorgi, Arpi Matossian-Rogers & Hilliard Festenstein

Department of Immunology, London Hospital Medical College, Turner Street, London El 2AD, UK

We have previously established the presence of a gene in mice (called Lus)1 which is dominant for the suppression of cytostasis, an experimental assay of cell-mediated immunity2. Here we describe the definition of a gene (segregating independently of Lus) that, in combination with the dominant gene Lusa, is homozygous recessive for a lymphoid hyperplastic disorder of T and B cells. We have called this gene Arp. The disease involves abnormalitities of lymphopoietic and other organs, and could be model system for regulatory defects of the immune system.

Cytostasis' is an in vivo/in vitre assay of cell-mediated immunity3. In our experiments mice were sensitized by injections of allogeneic lymphoid cells4. After 14 days we tested lymph node cells from sensitized mice in an in vitro cytostasis assay, using tumour cells as target cells.

Cytostasis is assayed by the uptake of radioactive thymidine by the tumour cells and is positive if uptake is inhibited by the effector cells. Both T and B cells (A. M.-R., L. DeG. and H. F., in preparation) are capable of causing cytostasis. Allogeneic cytostasis following sensitization across the H-2 barrier usually gives a positive result. However, we noted that whereas immunization of CBA/H (H-2k) mice with BALB/c spleen cells led to the production of cytostatic effectors against SL2 (H-2^d) tumour cells (a spontaneous Thy-1-positive DBA/2 lymphoma), immunization with B10.D2 (also H-2^d) spleen cells failed to generate anti-H-2^d effectors in the CBA/H (H-2^k) recipients. Mating B10.D2 with BALB/c mice produced F1 hybrids whose spleen cells also did not stimulate the production of cytostatic effector cells, suggesting the presence of a dominant suppressor gene in the B10.D2 mice. This finding was further studied and confirmed using (B10.D2×BALB/c)F₁×BALB/c backcross mice up to the fourth generation2 and beyond. Approximately 50% of backcross mice from each generation failed to stimulate the production of cytostatic effectors and were therefore carrying the cytostasis suppressor gene Lusa (ref. 1 and Tables 1, 2). These were selected for further backcrossing to BALB/c, to develop a strain congeneic with BALB/c at the suppressor locus. This was done up to the tenth generation

After the fourth backcross mating, we first noted the appearance of the hyperplastic disorder with abnormalities in the lymphopoietic and other organs in ~50% of 3-4-week old mice carrying the suppressor gene (Table 2), that is, cytostasisnegative mice. The disorder was manifested by gross hyperplasia of the thymus, spleen (Fig. 1), Peyer's patches and lymph nodes. There were concomitant histopathological changes in these

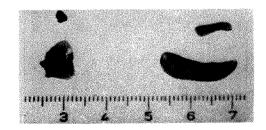

Fig. 1 Spleen and thymus from hyperplastic (right) and nonhyperplastic (left) cytostasis-negative littermates. Note the approximate 10-fold difference between the size of the organs.

Table 1 Data demonstrating the effects of the suppressor gene on the generation of cytostasis in CBA/H (H-2k) mice

	c.p.m. ± s.d. of SL2 (H-2d) tumour targets cultured with:	
Immunizing Bc Mice	Normal lymphocytes	Immune lymphocytes	% Inhibition of tumour growth
5th generation Cyts(+)	$28,727 \pm 2,618$	$10,383 \pm 648$	64
5th generation Cyts(-)	$28,724 \pm 2,618$	28.828 ± 1.680	0
5th generation Cyts(-) with hyperplasia	$28,724 \pm 2,618$	29.379 ± 1.131	0
6th generation Cyts(+)	$56,582 \pm 840$	20.378 ± 811	64
6th generation Cyts(-)	$56,582 \pm 840$	57.054 ± 3.188	0
6th generation Cyts(-) with hyperplasia	$56,582 \pm 840$	$64,123 \pm 6,047$	0
7th generation Cyts(+)	$33,060 \pm 1,472$	17.558 ± 1.416	47
7th generation Cyts(-)	$56,582 \pm 840$	$54,665 \pm 2,196$	4
7th generation Cyts(-) with hyperplasia	$56,582 \pm 840$	$53,053 \pm 2,728$	7

CBA/H mice were immunized intraperitoneally with 10^7 spleen cells obtained by biopsy from each backcross mouse, which was earmarked. 10–20 days after immunization, spleen cells were removed from the immunized mice under anaesthesia and cultured at a ratio of 10:1 with (SL2) tumour targets of DBA/2 origin in RPMI medium containing 5% fetal calf serum and antibiotics. Normal CBA/H lymphocytes were used as controls. The cultures were maintained for 48 h at 37 °C in a 4% CO₂, 10% N₂, 86% O₂ atmosphere. Tritiated thymidine was then added and the cultures were incubated for a further 16 h. The uptake of isotope, which was largely that of the tumour targets, was then measured and the inhibition of tumour growth calculated according to the following formula

% Inhibition =
$$100 - \frac{\text{c.p.m. of tumour cells + immune lymphocytes}}{\text{c.p.m. of tumour cells + normal lymphocytes}} \times 100$$

Cyts(+) and Cyts(-) are, respectively, mice producing and failing to produce cytostatic effector cells.

tissues (Fig. 2a, b) as well as lymphocytic and metamyelocytic accumulations in the liver (Fig. 3) and hyperplasia of the bone marrow. There was marked general thymic hyperplasia and thymic medullary hypercellularity ('thymitis') in the T lymphoid system, accompanied by paracortical hyperplasia of the lymph nodes. Evidence of germinal centre development was also seen in spleens and lymph nodes of affected mice, and plasma cells were abundant in the lymph node medullae.

The hypercellularity of bone marrow and spleen was due to two components: haemopoiesis, both erythroid and myeloid, and enlargement of malpighian follicles with occasional germinal centre formation (spleen). The presence of excess stainable iron was particularly evident in spleens of mice affected with the disease. There was no evidence of lymphoid or haematopoietic malignancy.

These lesions therefore represent a dyshaematopoiesis associated with lymphoid hyperplasia of both T and B lymphoid components (T more marked than B). Aspects of this pathological picture are consistent with the disorder being due to a primary haemolytic process or autoimmune disorder—with

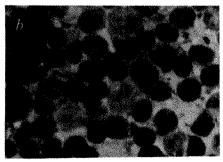

Fig. 2 Splenic impressions from hyperplastic and non-hyperplastic cytostasis-negative littermates. Note the presence of large numbers of blast cells with nucleoli (a) compared with predominantly mature leukocytes in the smears made from the non-hyperplastic spleens (b).

Fig. 3 Section of liver showing focal infiltration with metamyelocytes.

secondary hyperplasia as in NZB mice⁵. Although this disease is debilitating, fatality in affected mice observed up to 6 months was not greater than in controls.

As this lymphoproliferative syndrome was found in approximately half of the cytostasis-negative mice (those with the Lus^a cytostasis suppressor allele) from all backcross generations (Table 2), the involvement of a second gene in the control of the disorder was suggested, and was designated Arp. The syndrome occurs only in Lus^a-positive mice and so presumably Lus^a interacts epistatically with Arp. Because the disease occurs in 50% of the Lus^a-positive mice, the genotypes of the diseased

Table 2 Unigeneic segregation of the cytostasis suppressor gene allele Lus^a in (B10.D2×BALB/c)F₁×BALB/c backcross mice

Backcross* generation	No. of mice tested	No. of Bc mice Cyts(+)	No. of Bc mice Cyts(-)	No. hyperplastic
1	8	3	5)

the hyperplastic disorder in Cyts(-) backcross mice. NT, not tested.

*The same BALB/c male was mated with (B10.D2×BALB/c)F₁ females and four healthy Cyts(-) females selected from each backcross generation through to the tenth backcross.

†47% of Cyts(-) mice from the fifth and subsequent backcross generations presented a lymphohyperplastic syndrome described in the text.

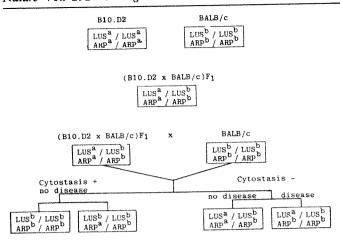

Fig. 4 Proposed genotype of B10.D2, BALB/c, (B10.D2× BALB/c)F₁ and backcrosses to BALB/c mice, with respect to the allelic expression of Lus^a (suppressor) and Arp^a protector (or Arp^b/Arp^b recessive hyperplastic) genes. Lus^a : cytostasis cytostasis (heterozygote co-dominant); Lus^b: suppressor enhancer; Arp^a : protector against hyperplastic disorder (heterozygote co-dominant); Arp^b : inducer of hyperplastic disorder (recessive homozygote). Genotype $Lus^a/Lus^b Arp^b/Arp^b$ suggests that epistasis of recessive Arp^b/Arp^b and co-dominant Lus" is needed to produce the hyperplastic disorder, or that protector Arp^a is a co-dominant allele preventing the development of the hyperplastic disorder.

mice with respect to the second gene must by Arp^b/Arb^b , and Lus^a and Arp genes segregate independently. Figure 4 shows the segregation of these genes and the proposed phenotypes of the parental strains and the crosses. (The disease is produced when the Arp b gene from BALB/c is homozygous and associated with Lusa.) There is no evidence of linkage of these genes to sex chromosome genes (data not shown).

We found that the disease was present in several mice of the first generation backcross, but was missed in the early matings of the first backcrossing programme. If female cytostasis-negative mice were randomly selected for backcrossing, there would be a probability of 1/16 that after four generations Arpa would still be segregating. However, these odds are increased because we selected for healthy mice (Arpa/Arpb heterozygotes) for backcrosses. Also, we selected for coloured coats, and Arpa might be linked to a coat colour gene. When the disease appeared, only healthy non-hyperplastic mice that failed to stimulate the production of cytostatic effectors were then selected for further matings. Two genetic traits were thus simultaneously selected, one associated with Lusa (cytostasis suppressor) and the other with Arpa (a healthy mouse). This selection procedure allowed for segregation of these two genes in all successive backcross matings, resulting in the same proportional representation of sick and healthy mice carrying Lus" at each future generation.

The way in which a genetic marker for a gene silent in its original context can, on transfer to a different genetic background, bring about a hyperplastic syndrome is intriguing. One can envisage that a human analogue of the suppressor gene may be transmitted to offspring with defective regulatory genes and thus promote neoplastic or hyperplastic cellular transformation.

We thank Dr J. A. Habeshaw for providing histopathological evidence and Dr P. Rogers and Professor G. D. Pegrum for helpful discussions. Cooperative interaction of B lymphocytes with antigen-specific helper T lymphocytes is MHC restricted

Barry Jones & Charles A. Janeway Jr

Department of Pathology, Yale University School of Medicine, New Haven, Connecticut 06510, USA

To produce antibody, bone-marrow-derived (B) lymphocytes generally require the synergistic action of a thymus-derived (T) lymphocyte, termed a helper T cell (Th)1. The interaction of Th with B cells is antigen specific and requires that both the T and the B cell be specific for physically linked antigenic determinants2. More recently it has been demonstrated in numerous systems that the interaction of Th and B cells is governed by antigens encoded within the major histocompatibility complex (MHC), such that Th and B cells must be identical in the I region of the MHC in order to cooperate efficiently3-5. This finding has been termed MHC restriction. However, studies using populations of T cells as a source of Th could be influenced by the presence of alloreactive T cells, suppressor T cells and other T-cells subsets, thus making interpretation difficult. Moreover, it has been proposed that MHC restriction governs not the interaction of Th with B cells, but rather the interaction of Th cells with antigen-presenting cells (APCs), whereafter the interaction of Th with B cells is said to be unrestricted. We have now attempted to clarify this situation by examining the interaction of soft agar colonies and clones of antigen-specific, MHC-restricted proliferating T cells 7.8 with purified B cells using several different assays. We conclude that the antigenspecific cooperative interactions between Th and B cells are themselves MHC restricted, and that B cells bearing the wrong MHC-encoded antigens cannot be activated by addition of APCs matched to the Th cell but differing from the B cell at MHC.

As a source of Th cells, we have used BALB/c (H-2^d) and BALB·B (H-2b) T cells primed with hen's egg albumin (OVA), cloned in soft agar and propagated in vitro according to Sredni et al.7. Evidence that these cells were antigen specific and MHC restricted in their proliferative responses is presented elsewhere8. The cells were then tested for their interaction with B cells in three different assays.

When antigen-specific, MHC-restricted T-cell colonies are treated with mitomycin C and added to B cells purified by elution from goat anti-mouse immunoglobulin (GaMIg) plates or by treatment of spleen cells with anti-Thy-1.2 antiserum and complement, intense B-cell proliferation ensues in the presence of specific antigen, peaking 48 h after initiation of the culture. This is not classically an assay for T-cell help, but seems rather to measure the polyclonal activation of B-cell proliferation by T cells. The data in Table 1 show that this response is antigen specific (furthermore, the response did not occur in the presence of 100 µg ml⁻¹ keyhole limpet haemocyanin), MHC restricted between T and B cells, and cannot be overcome by addition of mitomycin C-treated spleen cells as a source of APCs syngeneic to the Th but allogenic to the B cells (Table 1b). Figure 1 shows a second experiment in which the Th colony cells are titrated. In this instance, some induction of allogeneic B-cell proliferation is seen in the presence of mitomycin C-treated syngeneic spleen cells, but it is much less than that observed when Th and B cells are MHC matched, and is relatively little influenced by Th-cell dose. Although allogeneic B cells can be stimulated to proliferate in this manner, the response is meagre at best and occurs only in some experiments. Thus, we conclude that Th cells will induce B-cell proliferation in the presence of antigen, and that this interaction is MHC restricted largely or entirely between the Th and B cells themselves.

^{*} Mitomycin C-treated T cells were incubated with B cells and pulsed with ³H-thymidine after 48 h as described in Table 1 legend, but in these experiments, instead of OVA, normal rabbit serum (NRS) or rabbit anti-mouse brain (RaMBr) antiserum absorbed with mouse liver (×3) were added to the cultures at a final dilution of 1:100. † Background c.p.m. with NRS are shown in parentheses and have been subtracted from the responses with RaMBr to calculate \triangle c.p.m.

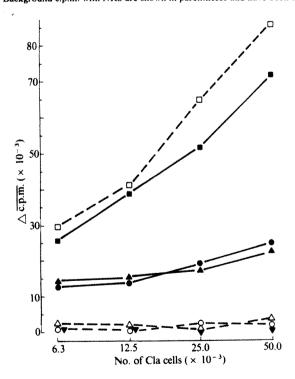

Fig. 1 BALB/c T_{OVA} colony cells (Cla) were treated with mitomycin C and titrated for their ability to induce proliferation in purified, non-immune, spleen B cells either in the absence (open symbols ——) or presence (closed symbols ——) of 2×10⁵ mitomycin C-treated BALB/c spleen cells added with OVA (100 µg ml⁻¹) as a supply of syngeneic antigen-presenting cells. 4×10⁵ B cells of the following strains were tested: BALB/c (□), BALB/K (○) or BALB/B (△). A control in the absence of B cells was performed (▼). After 48 h the cultures were pulsed with ³H-thymidine and the results are expressed as △ c.p.m., the difference between the response stimulated by OVA and controls in the absence of antigen.

Two objections could be raised to these experiments. The first is that the Th cells might in some way be suppressing the response of allogeneic B cells, and the second is that this response does not represent help, which involves both B-cell proliferation and differentiation to antibody-forming cells 10. We have therefore performed two further sets of studies to deal with these potential objections. In the first, Th- to B-cell interactions were initiated not with antigen but with rabbit anti-mouse brain antiserum (RaMBr), which activates T-cell proliferation in the presence of B cells in a non-MHC-restricted fashion¹¹. We have subsequently shown that it can also induce B-cell proliferation and polyclonal antibody production 48 h after initiation of culture in the presence of mitomycin C-treated Lyt-1⁺, 2⁻ cells. Because the T-cell colonies we have prepared are surface Ig⁻, Thy-1⁺, Lyt-1⁺, 2⁻, we treated them with mitomycin C and added them to purified B cells in the presence of normal rabbit serum (NRS) or RaMBr. Both normal BALB/c T cells and antigen-specific, MHC-restricted T-cell colonies induce a potent, polyclonal B-cell proliferative response in the presence of RaMBr but not NRS (Table 2), and this response is both T-cell dependent and unaffected by the MHC genotype of the responding B cell (Table 2b). Thus, these studies demonstrate that both normal T cells and MHC-restricted T-cell colonies can activate allogeneic B cells via RaMBr. It therefore seems unlikely that the failure of allogeneic B cells to respond to antigen in the presence of cloned T cells is due to some inhibitory effect of the T cells, but rather that it represents MHC-restricted activation of B cells by T cells.

To examine this question further, the ability of B cells to be induced to produce specific antibody by such Th cells was examined in an *in vitro* response to the hapten phosphorylcholine (PC) coupled to OVA, a system previously used by Bottomly and Jones¹² to explore the regulation of idiotype expression. In the present experiments, two colonies, one derived from BALB/c (H-2^d) and the other from the MHC-

[†] BALB/c OVA-specific T-cell colonies were prepared as described by Sredni et al.⁷ with the following modifications: T cells were prepared by passage over Ig-anti-Ig columns¹⁵, and the clones were stimulated with 5×10⁵ mitomycin C-treated spleen cells every 5-7 days. Colonies were tested 2-3 months after cloning. By immunofluorescence tests all cloned cells were Thyl.2⁺, Lyt-1.2⁺, Lyt-2.2⁻.

[‡] Background c.p.m. in the absence of antigen are shown in parentheses, and have been subtracted from responses. NT, not tested.

 $[\]S 2 \times 10^5$ mitomycin C-treated BALB/c spleen cells were added to the cultures.

Colony Cla was grown in bulk culture on B10·G spleen stimulator cells plus 20% T-cell growth factor (TCGF) (v/v) in the absence of OVA or H-2^d stimulators for 3 weeks, and then recloned by limiting dilution on BALB/c mitomycin C-treated spleen cells with 20% TCGF and OVA (200 μ g ml⁻¹). After 2-3 weeks six subclones were isolated, of which ClGl is an example.

Colony preparation was as described in Table 1 legend.

congeneic line BALB·B (H-2b), were tested for their ability to help BALB/c or C57BL/6J (H-2b) B cells. Furthermore, to test critically whether Th to B interactions were MHC restricted, we mixed purified B cells from the two strains with T-cell colonies of one type, cultured for 5 days with antigen, and assayed the plaque-forming cells (PFCs) before and after treatment with a monoclonal anti-H-2.5 antibody and rabbit complement. H-2.5 is present on H-2b but not H-2d cells, and thus the genotype of each PFC could be determined. If restriction operates at the level of Th to APC, and the genotype of the B cell is irrelevant as has been proposed6, then in these mixtures half of the PFCs should be H-2.5 positive and half negative, independent of the MHC restriction of the Th cells. In fact, although there is some nonspecific killing of PFCs by the antibody, as shown in the syngeneic mixtures, it is clear that there is little or no cooperation between Th cells and non-self B cells in this experiment (Table 3). One cannot argue, in this instance, that we have not added the necessary APCs, as a perfectly good PFC response is obtained in both cases. This experiment thus demonstrates conclusively that the MHC-restricted interaction in cooperation between Th and B cells in the response to soluble hapten-carrier conjugates occurs between Th and the B cells themselves, and does not involve non-MHC-restricted activation of B cells by Th

B cells bear large amounts of Ia antigens on their surfaces¹³. The interaction of Th with B cells is known to be restricted by Ia antigens^{3,14}. We interpret the present studies as showing that the function of these Ia molecules is to promote the interaction of Th cells with their appropriate target cells, the B cells. APCs also have Ia on their surface, and it is clear that Th-like cells can also interact with antigen in the context of APC Ia. Perhaps APCs, being non-antigen specific, are especially important for the initial activation of Th cells, after which Th cells preferentially interact with B cells bearing both the specific antigen bound by the B cell's immunoglobulin receptor and the appropriate Ia antigen. Thus, MHC restriction is seen as providing the Th cell with a mechanism of finding antigen only on the surface of those cells with which it can functionally interact, namely, B cells and APCs. If Th- to B-cell interactions were not themselves MHC restricted, this interpretation would not make sense. However, the present studies show that this interaction is indeed MHC restricted between Th and B cells.

The present report also describes two convenient and rapid methods for measuring Th- to B-cell interactions in proliferation assays. The polyclonal B-cell response to antigen in the presence of both Th colonies and cloned Th is not fully understood. Because it requires 1,000 times as much antigen as the in vitro specific anti-PC PFC response to PC-OVA, it may be that all B cells acquire a small amount of antigen at high antigen dose, independent of their immunoglobulin receptor, and thus can be

Table 3 Cooperation between OVA-specific T-cell colonies and B cells is MHC restricted in the response to PC-OVA

			ti-PC-PFCs per cells with Th col	
B cells	Treatment to PFCs	0	II 2 B6d (H-2 ^d)	II 2 D4b (H-2 ^b)
BALB/c (H-2 ^d)	0	3	112	10
BALB/c	Y - 3 + C		75 (33%)	
C57B1/6 (H-2b)	0	1	8	106
C57B1/6	Y - 3 + C			2 (98%)
BALB/c+C57BL/6	0		153	191
BALB/c+C57BL/6	Y-3+C		102 (33%)	18 (91%)

B cells were normal spleen cells treated with anti-Thy-1.2+C followed by anti-Lyt-1.2+ anti-Lyt-2.2 plus C. 3×106 viable cells placed in 1 ml culture with 0.1 µg ml⁻¹ PC-OVA and 10⁵ helper T cells. Five days later, plaque-forming cells (PFCs) were evaluated on PC-coupled sheep red blood cells. Values represent means of triplicate cultures. After culture, cells were treated with rabbit complement, or with monoclonal anti-H-2.5 antibody Y-3, which was raised in a BALB/c anti-H-2b immunization and kills 100% of H-2b spleen cells to a titre of 1:108, but does not react with H-2d. Helper T-cell colonies from BALB/c or BALB·B mice were prepared as described in Table 1 legend. Numbers in parentheses give per cent reduction in PFC response after treatment with anti-H-2b monoclonal antibody and complement.

induced to respond by the Th cells. If this is the case, it might imply that the immunoglobulin receptor is not involved in this form of B-cell proliferation. We are now investigating the role of the immunoglobulin receptor in this response, and also whether such cells subsequently secrete immunoglobulin. The assay involving RaMBr is reported in detail elsewhere. We forsee a role for this assay in assessing T- and B-cell function in man, as RaMBr-mediated T to B interactions do indeed lead to immunoglobulin production (J. P. Tite and B.J., unpublished), and because the interaction is not MHC restricted, the assay could be used between any two individuals.

We conclude that the interaction of Th cells with B cells is antigen specific and is itself MHC restricted. This conclusion supports the notion that Ia on B cells is critically important in promoting appropriate interactions with Ia-restricted helper T cells.

Distinct genes for fibroblast and serum C1q

Complement component C1 is composed of three subcomponents, C1q, C1r and C1s (refs 1, 2). The problem of which cells produce C1 in vivo has been controversial, and many cell types³⁻⁹ have been reported to synthesize these molecules. Material antigenically similar to C1q was reported10 to be synthesized and secreted by human and rat fibroblast cell lines. Reid and Solmon¹¹ subsequently showed that C1 haemolytic activity was secreted into the medium of cultured human fibroblast cell lines, and that the form of the C1q was unusual in that it had an apparently higher molecular weight than did C1q isolated from normal serum. As fibroblasts are an abundant cell type, this observation suggested that they might be a major contributor to serum C1q, secreting C1q precursor, pro-C1q. We describe here a genetic defect of serum C1q. Homozygotes for this defect do not produce functional plasma C1q, although they seem to produce normal fibroblast C1q. Heterozygotes produce both normal and defective serum C1q. This suggests that different genes code for the chains of C1q produced by fibroblasts and for those produced in serum.

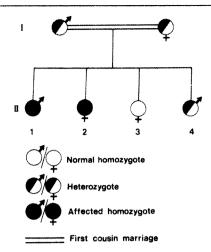

Fig. 1 Family tree showing the inheritance of the gene responsible for the production of the non-functional serum C1q. This condition appears to behave as an autosomal recessive in which both affected siblings, II 1 and II 2, are homozygous for the defective gene, and both parents and sibling II 4 are heterozygous. Skin biopsies were obtained from II 1 (SSF) and II 2 (RKF).

A family has been described¹² in which two siblings are totally deficient in serum C1q activity. The eldest child, a boy, suffers from a lupus-like syndrome and glomerulonephritis. The younger sister shows no evidence of nephritis clinically, but has cutaneous vasculitic lesions of the face and hands. Both children have a non-functional, but immunologically cross-reacting serum C1q. The normal and defective C1q in the family can be distinguished on Ouchterlony double-diffusion gels¹². The defective serum C1q is slightly less mobile on SDS-polacrylamide gel electrophoresis (PAGE) in non-reducing conditions than is normal C1q (K.B.M.R., unpublished results), as shown in Fig. 3a. In addition, the patients' serum C1q behaves anomalously compared with normal C1q on a Sephadex G-200 column, and can be separated in non-dissociating conditions. Of two other siblings, one is entirely normal, and the other, apparently heterozygous, has both functional and nonfunctional C1q. The parents are first cousins, and they also have functional and non-functional C1q. Figure 1 shows the family

To determine whether the fibroblasts of these patients produce the haemolytically inactive C1q that is found in their serum, we established skin fibroblast cultures, designated SSF (male) and RKF (female), from each of the two affected homozygous siblings. Human fibroblasts, designated Bu, from a C1q normal individual were used as the control culture. Cells were grown for 7 days in RPMI 1640 medium in the presence of 10% inactivated fetal calf serum (FCS), and the samples from days 0 and 7 compared. The FCS was inactivated by heating at 56 °C for 45 min, which destroys most, but not all, of the bovine C1 haemolytic activity. As seen in Fig. 2, SSF and RKF cultures gave the same titres of C1 haemolytic activity as did the control fibroblasts. Assay conditions indicated that these fibroblasts were producing C1r and C1s, in addition to active C1q, a finding consistent with previous work 11.

To characterize the structure of the fibroblast C1q produced by the serum C1q-deficient patients, immunoprecipitates derived from the supernatants of labelled cultures of SSF, RKF and Bu were compared on SDS-PAGE (Fig. 3a, b). These cultures were also assayed for haemolytic activity and found to be positive.

Cold carrier serum C1q was added to each sample of labelled fibroblast medium before immunoprecipitation. The immunoprecipitates were run on SDS-PAGE in reducing and non-reducing conditions. Figure 3a shows the positions of the cold carrier serum C1q, after protein staining. The reduced sample (lane 1) shows the three chains of serum C1q, A, B and C, at

apparent molecular weights 34,000, 31,000 and 27,000 (refs 13, 14), and the heavy and light chains of the rabbit immunoglobulin. The non-reduced sample (lane 2) shows the A-B and C-C dimers of C1q and the intact rabbit immunoglobulin. Figure 3b shows an autoradiograph of the whole gel. As found previously with fibroblast cultures 11, the larger-molecular-weight C1q does not enter the gel in the non-reduced form (lanes 5-7). When reduced, the radioactively labelled C1q immunoprecipitates from the three fibroblast cultures (lanes 2-4) all show the same two bands, with apparent molecular weights of 47,000 and 42,000. These same two bands were previously shown to be synthesized by fibroblasts11. Both reduced and non-reduced samples show radioactive bands near the top of the gel. The identity of these bands is not certain, but they are probably fibronectin which could bind to the collagenous part of the cold carrier Clq, present in the immune aggregates, in a similar manner to the binding of fibronectin to denatured collagen (see, for example, ref. 15).

The results clearly indicate that the C1q secreted into the medium of the fibroblast cultures, derived from the two serum C1q-deficient siblings, has haemolytic activity comparable with that of the control culture. The radiolabelled immunoprecipitates from the culture medium also show no apparent differences between the patients and the control.

If fibroblasts were a major source of serum C1q, patients with a non-functional circulating C1q might be defective in a gene

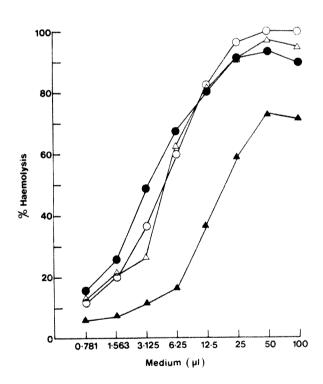

Fig. 2 Assay of component C1 haemolytic activity of day 0 control, and day 7 medium collected from fibroblast cultures of Butler (Bu), RKF and SSF. Preparation of the buffers and reagents used in the haemolytic assays was performed as described by Reid 5. Aliquots (100 µl) of doubling dilutions of the cell culture media were incubated with $100 \,\mu l$ of EAC4 cells (1×10^8) cells ml⁻¹) at 30 °C for 20 min, and then spun down at 2,000 r.p.m. for 10 min. The cell pellet was resuspended in assay buffer and incubated at 30 °C for 40 min, then component C2 (0.1 ml, 200 effective mol ml⁻¹) was added and the mixture incubated at 30 °C for 15 min. 0.1 ml of EDTA buffer, pH 7.4, was added and finally 0.2 ml of guinea pig serum, diluted 1/30 with isotonic buffer, pH 7.4, containing EDTA, was added and incubated at 37 °C for 30 min. After addition of 1.0 ml 0.15 M NaCl, the mixture was spun at 2,000 r.p.m. for 10 min and the degree of lysis determined by reading the A_{412} of the supernatant. \bigcirc , Bu; \triangle , RKF (female); ●, SSF (male); ▲, day 0 control.

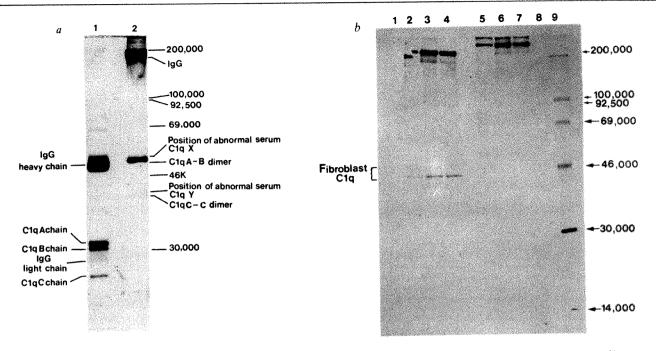

Fig. 3 a, The three fibroblast cell lines, Butler, RKF and SSF, were labelled over 72 h with 100 μ Ci ³⁵S-methionine, 16.3 μ Ci ¹⁴C-proline and 16.3 μ Ci ¹⁴C-glycine per flask of 2×10^6 cells. The radioactive amino acids were added directly to the medium containing inactivated FCS. A solution of carrier subcomponent C1q, prepared according to Reid¹⁷ (30 μ l of 3.8 mg ml⁻¹), was added to the 30 ml culture medium collected from the three fibroblast cell lines. The medium was made 10 mM with respect to EDTA, and then concentrated to ~4 ml in an Amicon Diaflo 50-ml cell using a PM10 membrane. The concentrate was mixed with enough heat-inactivated rabbit anti-human serum subcomponent C1q to precipitate all the unlabelled carrier subcomponent C1q added. The rabbit anti-C1q was prepared according to Reid et al. 13. The concentrate plus antiserum was incubated at 37 °C for 2 h, and then at 4 °C overnight. The immunoprecipitate formed was washed five times with 0.3 ml of 10 mM EDTA/150 mM NaCl, pH 7.4. After the final wash the samples were electrophoresed on a polyacrylamide gel in the presence of SDS as described by Fairbanks et al. 18. The gel was stained for 1 h and then destained overnight. Lane 1, cold reduced serum C1q, lane 2, non-reduced cold serum C1q. Molecular weight markers (14C-methylated protein mixture CFA.610, Radiochemical Centre) were myosin (MW 200,000), phosphorylase b (100,000 and 92,500). bovine serum albumin (69,000), ovalbumin (46,000), carbonic anhydrase (30,000) and lysozyme (14,300). Standards were run in reducing conditions. The mobility of the defective serum C1q in non-reducing conditions is indicated on this gel. This was determined in a parallel experiment (K.B.M.R., unpublished results). X and Y correspond to what are thought to be the A-B and C-C dimers of the abnormal serum C1q. b, The gel was impregnated with diphenyloxazole in dimethyl sulphoxide by the method of Bonner and Laskey¹⁹, dried and exposed to RP Royal X-Omat film at -70 °C for 2 weeks. Lane 2, reduced Bu; 3, reduced RKF; 4, reduced SSF; 5, non-reduced Bu; 6, non-reduced RKF; 7, non-reduced SSF.

coding for a processing enzyme of fibroblast C1q. In this event, one could not expect the heterozygote parents and sibling to have normal as well as abnormal circulating C1q, as codominant expression is not expected with a defect in a processing enzyme. Thus, these results strongly suggest that a cell type other than fibroblasts is responsible for the synthesis of serum Clq, and that there are distinct genes for the fibroblast Clq and serum C1q. The products of these genes would be two antigenically and physicochemically different C1q molecules.

We thank Dr R. H. R. White for permission to study these patients, and Drs M. Crumpton, P. N. Goodfellow and W. F. Bodmer for helpful discussions.

Dispermic origin of XY hydatidiform moles

Koso Ohama*, Tadashi Kajii†, Etsuji Okamoto*, Yasuhiko Fukuda‡, Kiyoshi Imaizumi†, Masato Tsukahara†, Kunihiko Kobayashi† & Keiji Hagiwara†

* Department of Obstetrics and Gynecology and ‡ Surgery, Hiroshima University School of Medicine, Hiroshima, Japan 734 † Department of Pediatrics, Yamaguchi University School of Medicine, Ube, Japan 755

Complete hydatidiform mole is an abnormal human pregnancy with grossly swollen chorionic villi, usually with a 46,XX karyotype, and with a propensity to malignancy1. The XX moles originate from fertilization of an 'empty egg' (resulting from either enucleation or inactivation of the female pronucleus) by a haploid sperm and its subsequent duplication^{2,3}, a process called diploid androgenesis. XY moles, although infrequent, are of special interest because their origin must differ from that of the XX moles. Two XY moles have been studied for their origin, but the results were inconclusive^{3,4}. We describe here a study of four XY moles, and provide evidence that they result from the fertilization of an empty egg by two haploid spermatozoa.

The macroscopic and microscopic findings of the four XY moles were indistinguishable from those of XX moles. The karyotypes of cells cultured from the molar tissue of the four patients were 46,XY. Q- and R-band chromosome heteromorphisms², histocompatibility leukocyte antigen (HLA) specificities, phosphoglucomutase 1 (PGM₁) and esterase D

^{*} Age at expulsion (days after last menstrual period in hydatidiform mole).

(ES-D) genotypes were studied in the four XY moles and their parents. HLA-A and -B specificities were studied using peripheral blood lymphocytes from the parents and cultured molar fibroblasts by the standard National Institutes of Health two-stage microcytotoxicity test⁵. PGM₁ and ES-D genotyping was carried out on parental red cells and on uncultured molar villi with starch gel electrophoresis^{6,7}. These genetic markers were reliable in our hands in the study of the origin of XX moles (ref. 2 and unpublished data). The chromosomal markers are situated close to the centromeres and thus are usually free from meiotic crossing-over, while HLA and enzyme gene loci are situated relatively far from the centromeres, and thus may occasionally be subject to cross-over and resulting recombination.

The results of these studies are shown in Table 1. Mole A inherited both chromosomes 15 and HLA-B specificities exclusively from the father. Similarly, mole B showed an exclusively paternal inheritance of both chromosomes 15 and 21, as well as HLA-A and -B specificities. Mole C inherited both chromosomes 15 from the father. Mole D inherited pairs 3, 13 and 22 exclusively from the father. Thus, all four moles were androgenetic in origin. Further, each of the four moles had both homozygous (a paternal marker transmitted to the mole in duplicate) and heterozygous (both paternal markers transmitted to the mole) genetic markers. The fact that both homozygous and heterozygous chromosomal heteromorphisms were observed in each of the four moles indicates that the moles resulted from dispermy, that is, entry of an X and Y sperm into an 'empty egg'. Entry of a diploid spermatozoon resulting from tetraploid spermatogonia cannot be ruled out but is less likely. The results of the HLA studies do not support the cytogenetic findings, but this could well be a chance occurrence (one in eight).

We are aware of 121 complete moles karyotyped since 1977: 80 by us and 41 in the literature 3,4,8-10. This, excluding an isolated case report4, would give five XY moles out of 120 karyotyped, a rate of 4%. Dispermy would result in XX, XY and YY sex chromosome constitution, at a 1:2:1 ratio. YY moles are lethal, while XX dispermic moles are not. Therefore, some 2% of XX moles would also be the product of dispermy, a variety yet to be identified.

Mole B in our series is worthy of comment. The human chorionic gonadotropin (HCG) level in the mother remained high after expulsion of the mole, and roentgenography 8 weeks after expulsion revealed in the right lung a 15×13 mm rounded shadow not seen before. Chemotherapy was started and the urinary HCG level fell to normal in 10 weeks, while the pulmonary shadow remained unchanged 18 months after treatment. We proposed that the propensity to malignancy of complete moles is associated with single chromosomal mutation

that is of necessity homozygous in the 46, XX variety². This explanation might only apply to the XY dispermic moles, in which each spermatozoon would contribute the same chromosomal segment carrying the causative mutation. It would be interesting to know whether such a propensity is more prevalent in one of the two classes of complete mole

RNA is synthesized at the nuclear cage

D. A. Jackson, S. J. McCready* & P. R. Cook

Sir William Dunn School of Pathology and * Botany School, University of Oxford, Oxford OX1 3RE, UK

The photomicrographs of 'genes in action' taken by Miller and colleagues strikingly illustrate transcription of eukaryotic genes by RNA polymerase moving along the DNA1,2. Although completed transcripts may be associated with sub-nuclear structures3-7, the view that a mobile polymerase processes along the DNA remains unchallenged. Here we examine an alternative view-that transcription occurs as DNA passes through a transcription complex fixed to a sub-nuclear structure, and we show that transcribed sequences are closely associated with a sub-nuclear structure that we call a nuclear cage.

When nuclei are isolated by conventional procedures, their DNA is invariably broken, mainly by endonucleolytic nicking8. However, if living cells are lysed in a detergent, 2 M salt and chelating agents, structures are released which resemble nuclei 4.9-12. Such nucleoids contain naked histone-free DNA packaged within a flexible cage of RNA and protein. Some

^{-,} Neither of maternal markers transmitted to the mole, indicating its androgenetic origin. □, f a, b, c and d are symbols and do not represent specific heteromorphisms. A paternal market transmitted in duplicate to the mole [1], Both of paternal markers transmitted to the mole. A, B, C, D refer to the four moles studied.

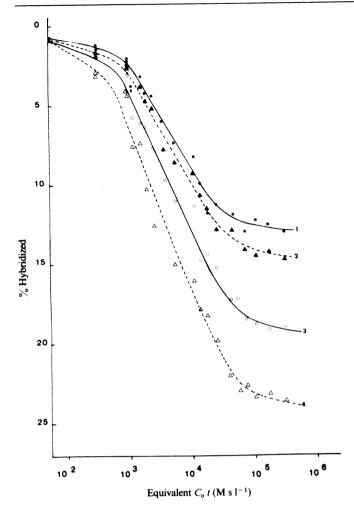

Fig. 1 Cage-associated DNA is enriched in sequences complementary to nucleoid RNA. Four different samples of cage-associated DNA containing 100% (sample 1), 35% (2), 14% (3) and 5% (4) of the DNA associated with undigested nucleoids were labelled by nick-translation, denatured and the per cent of the DNA forming a hybrid with an excess of nucleoid RNA determined. Nucleoids (prepared from cells labelled with ³H-thymidine) were incubated with various amounts of *EcoR*1 and the cages, and any associated DNA, sedimented free of unattached DNA¹⁸. The pellet was solubilized in proteinase K and SDS and the amount of DNA remaining cage associated determined by scintillation counting. The cage-associated DNA was purified, completely fragmented with EcoRI to yield populations of fragments with similar sizes¹⁸ and labelled by nick-translation³¹ using ³HdCTP (58 Ci mmol $^{-1}$) to yield products with specific activities of $50-70\times10^6$ d.p.m. per μg. After heat denaturation, these single-stranded probes had sizes between 100 and 200 nucleotides (determined by gel electrophoresis). RNA was purified from nucleoids and hybridized in excess (RNA: DNA, 50 mg ml⁻¹: 25 ng ml⁻¹) to the labelled DNA and the per cent of the DNA forming a hybrid determined essentially as described by Levitt et al.32 Self-annealing of the probe, in the presence of an excess of tRNA, never exceeded 2% and has been subtracted from the values presented. During the very long incubation required to achieve high equivalent C_0t values, <5% of the probe became acid soluble.

nucleoid proteins resemble those of various sub-nuclear structures isolated by other workers¹³⁻¹⁷. Their DNA, which is looped by attachment to the cage, is supercoiled and so must be unbroken. Therefore, these nucleoids might be expected to contain unbroken RNA.

We first studied whether DNA close to the cage was richer than total DNA in transcribed sequences. Four types of DNA were prepared by incubating HeLa nucleoids with various amounts of *Eco*RI; then cages, and any associated DNA, were sedimented free of detached fragments to yield pellets which retained various amounts of DNA¹⁸. This cage-associated DNA was purified and hybridized with total nucleoid RNA (Fig. 1). (As nucleoids contain all the nuclear RNA, this is equivalent to nuclear RNA.) The cage-associated DNA hybridized to a

greater extent than total nuclear DNA (sample 1), for example, 23% of the DNA from cages which retained 5% of the total (that is, sample 4) is complementary to nucleoid RNA. Assuming that only one strand is transcribed, about half this sample of cage-associated DNA contains transcribed sequences—a remarkable enrichment.

We next determined whether nascent RNA was attached to the cage. When HeLa cells are incubated with 3 H-uridine for 1 or 15 min, >95% of the cellular radioactivity which is insoluble in trichloroacetic acid subsequently co-sediments with nucleoids (unpublished results and ref. 4). We tested the possibility that it is entangled in the cage network or the high concentration of DNA by determining whether it could be detached with DNA from the cages. Cells were labelled with [Me^{-14} C]thymidine (0.005 μ Ci ml⁻¹; 56 mCi mmol⁻¹) for 24 h, followed by 3 H-uridine (10 μ Ci ml⁻¹) for 2.5 min. (Actinomycin D (0.08 μ g ml⁻¹) was present during, and 30 min before, the 3 H pulse to suppress ribosomal RNA synthesis ¹⁹.) Nucleoids were

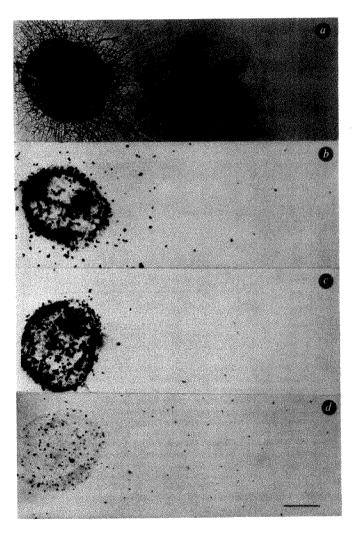

Fig. 2 RNA is attached to the cage. a, An electron micrograph of a nucleoid spread by Kleinschmidt's procedure ¹² illustrating the cage and the skirt of tangled DNA fibres. b-d, Autoradiographs of spreads²⁰ after labelling: b, HeLa cells in vivo for 24 h with [Me- 3 H]thymidine (58 Ci mmol $^{-1}$; 0.05 μ Ci ml $^{-1}$); c, cells in vivo for 2.5 min with [5,6- 3 H]uridine (46 Ci mmol $^{-1}$; 250 μ Ci ml $^{-1}$); d, nucleoids in vitro by transcribing nucleoids for 15 min using E-coil RNA polymerase (see ref. 21; 3 units per assay; [5,6- 3 H]UTP, 52 Ci mmol $^{-1}$, 20 μ Ci ml $^{-1}$). The reaction was stopped by the addition of NaCl to 2.0 M. So that silver grains can be easily seen and counted in b-d, DNA is shadowed but not stained and can be seen only at higher magnifications. Nascent RNA cannot have been torn from the DNA—and so lost—during the violent spreading because the same total aumber of grains lie over the DNA of spread and unspread nucleoids (results not shown). Scale bar, 5 μ m.

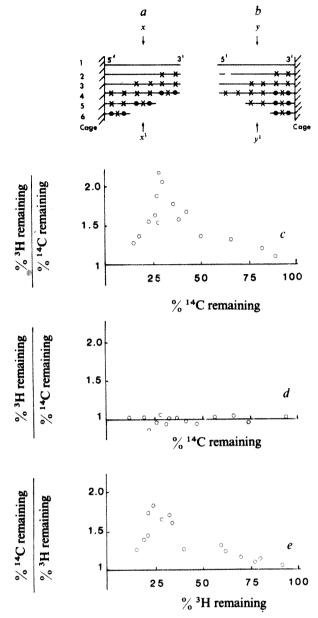

Fig. 3 RNA is attached at the 3' end. a, A simple model for labelling and cutting RNA attached at the 5'end. (1) A completed strand of RNA (attached at its 5' end to the cage. Cells are labelled for 2 min with 14C-uridine (×) followed by 1 min with ³H-uridine (•). (2, 3), Some nascent RNA molecules complete synthesis after the addition of ¹⁴C but before the addition of ³H, so becoming only ¹⁴C-labelled, whereas others (4-6), which initiate during the pulses, become labelled with both ¹⁴C and ³H. Digestion with ribonuclease (that is, cutting between x and x') detaches ¹⁴C and ³H in roughly equal proportions. Therefore, on digestion, the ratio (%3H remain-C remaining) remains at about unity. b, An array of molecules labelled as in a are attached at the 3' end. Cutting between y and y' detaches ¹⁴C but not ³H: therefore, the ratio is greater than unity. These models are gross oversimplifications and we use them only to illustrate whether or not a label becomes enriched. c-e, The 3' end of nascent RNA resists detachment by ribonuclease. HeLa cells $(5 \times 10^7 \,\mathrm{ml}^{-1})$ were incubated at 37 °C with $[U^{-14}C]$ uridine (490 mCi mmol⁻¹) and $[5,6^{-3}H]$ uridine (46 Ci mmol⁻¹) as indicated. Actinomycin D (0.08 µg ml⁻¹) was present 30 min before, and during, the labelling. Labelling was stopped by the addition of 50 volice-cold phosphate-buffered saline containing 10 mM uridine, the cells were pelleted and washed, and nucleoids isolated and diluted to 0.2 M NaCl and ~2 with 10 mM Tris (pH 8.3). They were then incubated with pancreatic ribonuclease (2-500 ngm ml-1) for 0-30 min at 37 °C and the reaction was stopped by addition of NaCl to 2 M. The per cent of label remaining associated with cages was determined by filtration²⁰. Control experiments using mixtures of labelled RNA and nucleoids showed that experiments using mixtures of labelled RNA and nucleotes 88% of the RNA could be filtered free of the cages. Labelling was for: c, 2 min with 14 C-uridine (2 μ Ci ml⁻¹) followed by 1 min with 3 H-uridine (200 μ Ci ml⁻¹); d, 3 min with both 3 H-uridine (200 μ Ci ml⁻¹) and 14 Curidine $(2 \mu \text{Ci ml}^{-1})$; e, 2 min with ³H-uridine $(100 \mu \text{Ci ml}^{-1})$ followed by 1 min with ¹⁴C-uridine $(4 \mu \text{Ci ml}^{-1})$. In these conditions sufficient label was incorporated to be counted accurately; for example, filters bearing undigested nucleoids contained about 10^4 and 2×10^3 d.p.m. of 3H and ^{14}C respectively.

isolated, incubated with EcoRI and the amount of the two labels remaining associated with cages was determined after filtering them free of detached DNA²⁰. In one typical experiment, when 90% of ¹⁴C (that is, DNA) was detached, < 5% of the ³H (RNA) was lost. (A control experiment showed that >80% of the ³H but none of the ¹⁴C could be detached by ribonuclease.)

A second experiment confirms that nascent RNA is not simply entangled in DNA. When nucleoids are spread on an air/aqueous interface their DNA, initially confined within the cage, forms a huge skirt which is attached to, and surrounds, the collapsed cage ¹² (Fig. 2a). If RNA were entangled in DNA we would expect its distribution to reflect that of spread DNA. The latter is obtained from autoradiographs of spreads prepared from cells containing uniformly labelled DNA (Fig. 2b): 55% of the DNA is outside the cage ²⁰. However, when cells are pulse-labelled with ³H-uridine for 2.5 min, >90% of the grains lie over the cage in each of 20 spreads selected at random (Fig. 2c). This is so whether or not the DNA has been lightly γ ray-irradiated (9.6 J per kg) to release supercoils ^{9.11} (results not shown).

The following controls demonstrate that RNA made in vitro can escape with the DNA from the cage and does not stick nonspecifically to the cage network. RNA was synthesized in vitro by incubating nucleoids with Escherichia coli RNA polymerase, ³H-UTP and the appropriate precursors²¹. The transcripts co-sediment with the nucleoids²¹ and are spread by Kleinschmidt's procedure; 34% of the autoradiographic grains are found over the skirt (Fig. 2d). Furthermore, digestion with EcoRI (using conditions which detached 79% of the DNA) detaches 75% of this RNA labelled in vitro so that it can then be filtered free of the cages. (The conditions for transcription and filtration are described in the legends to Figs 2 and 3.) This RNA made in vitro is not as tightly associated with the cage as that synthesized in vivo. We next determined whether this tight association was specific.

A 'cap' containing methylated bases is synthesized at the 5' end of nascent RNA as transcription begins²²⁻²⁴. Therefore, ³H-methionine can be used to label caps; however, this label is also incorporated into proteins, DNA and other methylated bases within RNA chains, especially into those within ribosomal RNA molecules. We suppress the latter using actinomycin D^{19,23}. We established what proportions were incorporated into these different fractions by labelling cells for 15 min with ³H-methionine. Of the label in nucleoids, 75% was solubilized by proteinase K and SDS, and so must be in protein, and 23% was recovered in RNA (Table 1). As others have found^{25,26}, 36% of the label in RNA was in caps, the remainder being in internal residues within the original RNA chains (control sample in Table 1).

Table 1 Distribution of incorporation of ³H label into different fractions on labelling RNA

Amount label remaining (c.p.m. × 10 ⁻³)			
Control	RNase treated		
600 (100%)	600 (100%)		
138 (23%)	68 (11%)		
90.2 (15%)	24.6 (4.1%)		
50.0 (8.3%)	48.2 (8.0%)		
	Control 600 (100%) 138 (23%) 90.2 (15%)		

Cells were labelled for 15 min with L-[Me-³H]methionine (50 μCi ml-¹; 78 Ci mmol-¹), and nucleoids isolated and diluted to 0.2 M NaCl and 2×10⁶ ml-¹ with 10 mM Tris (pH 8.0)^{4.1¹}. Actinomycin D (0.08 μg ml-¹) was present 30 min before, and during, the labelling. Nucleoids were then incubated with or without pancreatic ribonuclease (5 μg ml-¹) for 15 min at 37 °C, the reaction was stopped by the addition of NaCl to 2 M and the nucleoids were pelleted through a cushion of 7.5% sucrose containing 2 M NaCl. The pellet was digested with deoxyribonuclease (5 μg ml-¹) for 20 h and then proteinase K and SDS¹8. Next, RNA was purified³0 and the proportion of label in caps and internal residues in the RNA was determined after digestion with RNase A and T2 followed by column chromatography: mononucleotides and caps eluted in fractions containing +1 and +5 charges, respectively²³.25.26°. The amount of ³H in the different fractions is given in the table with percentages in parentheses. The amount of RNA detached (75%) by the ribonuclease from the pelleted cages was determined from an identical experiment in which cells were labelled with [5,6-³H]uridine (46 Ci mmol-¹; 10 μCi ml-¹) rather than the ³H-methionine.

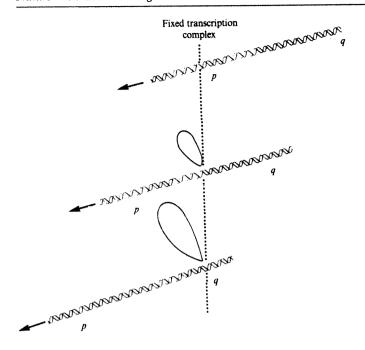

Fig. 4 A model for transcription. a, A fixed complex transcribes DNA between p and q. b,c, RNA is synthesized as DNA passes through the complex, the nascent RNA chain being attached at both ends forming a loop. Transcription of a helical template—itself attached to the cage—to yield attached transcripts poses a number of topological problems. If the polymerase rotates about the helical axis then the transcript can be separated from its template during synthesis by cutting one and passing the other through the cut (there is a precedent for cutting RNA during 'splicing'). Alternatively, a fixed topological relationship might be maintained between the cap and 3' end, perhaps by attaching both to the polymerase, so that if one rotates then so does the other. If DNA rotates, then supercoiling is inevitably induced elsewhere in the DNA and must be stored or released (for example by a nicking-closing activity).

If nascent RNA is attached at its 5' end, caps should resist detachment by ribonuclease. Therefore, we incubated ³H-methionine-labelled nucleoids with sufficient ribonuclease to detach 75% of nascent RNA. Next, cages and any associated RNA were sedimented free of detached RNA and the amounts of label in the different fractions determined (Table 1). The ribonuclease treatment did not affect the quantity of label recovered in protein or DNA (results not shown) whereas it halved that in RNA. This reduction was almost entirely due to the loss of label in internal residues with negligible loss in caps. Therefore, removal of 75% of the body of the chain detaches few, if any, caps.

We have attempted to demonstrate attachment at the 3' end as follows. Cells were incubated for 2 min with 14C-uridine and then for 1 min with ³H-uridine. The doubly labelled nucleoids were then incubated with ribonuclease, the detached RNA removed by filtration and the percentage of the labels remaining associated with the cages determined. If RNA is attached at random, 14C and 3H will be detached from the cages in equal proportions, that is, the normalized ratio (% ³H remaining): (% ¹⁴C remaining) will remain at unity independently of the amount of ¹⁴C remaining. On the other hand, if the 3' end is attached, detachment of RNA will lead to a relative enrichment of ³H: the ratio will increase above unity as the amount of 14C remaining decreases (Fig. 3a, b). (Attachment at both ends cannot be distinguished from 3' attachment using this labelling regime.) The results are consistent with attachment at the 3' end because the ³H resists detachment. For example, removal of all but 30% of 14 C leaves 54% of 3 H (thus, the ratio in Fig. 2c is 54:30 = 1.8). Experiments with simultaneous labelling and label reversal (Fig. 3d, e) rule out labelling artefacts.

Three points should be borne in mind in discussing these results. First, we are concerned mainly with heterogeneous

nuclear RNA as we have generally labelled in actinomycin D to suppress ribosomal RNA synthesis. Second, our pulse times should label many unfinished molecules. [Heterogeneous nuclear RNA—1,500–50,000 nucleotides²³—is synthesized at ~5,000 nucleotides per min (ref. 27)]. The third point concerns the anchorage by polymerases of 3' ends to DNA and so to the cage. We would expect polymerases to dissociate from the DNA in the 2 M NaCl used to make nucleoids and although nucleoids contain no polymerase activity²¹, we cannot preclude anchorage by some—perhaps undiscovered—subunit of the polymerase. However, if polymerase does hold the 3' ends in this way, it must do so close to the cage because neither transcript nor its template is readily detached by *Eco*RI.

We have demonstrated that transcribed sequences are closely associated with a sub-nuclear structure that we call the nuclear cage. Furthermore, nascent RNA is attached at the 5' cap—and perhaps at the 3'end—to the cage. The striking micrographs illustrating polymerases processing along the DNA unattached to any larger structure are obtained only after disruptive spreading or with unusually hyperactive genes which may be very special cases. (For example, lampbrush loops and amplified ribosomal genes in amphibian oocytes.)

A trivial explanation is consistent with our results. Perhaps nascent RNA, which is synthesized throughout the nucleus in vivo, sticks to the cage when nucleoids are prepared. We think this extremely unlikely: nearly all this RNA would have to stick specifically at the 5' end and remain stuck during filtration or spreading, even though the control experiments show that RNA synthesized in vitro has little if any, affinity for nucleoids. A second explanation is that a polymerase initiates at the cage and moves away to yield a transcript attached at its cap. However, this cannot readily explain why, in the presumed absence of polymerase, the 3' end resists detachment by ribonuclease. Alternatively, transcripts may be generated as DNA passes through a fixed transcription complex to yield transcripts attached at both ends (Fig. 4). Whichever proves to be correct, it seems that the cage must have an important role in transcription. As replication is initiated by attaching sequences to the cage²⁰ (see also refs 28, 29), perhaps genes are also activated during differentiation by attachment.

We thank Professor H. Harris FRS and Dr B. S. Cox for their encouragement and the Cancer Research Campaign and the SRC for support.

Developmental expression of a Drosophila actin gene encoding actin I

Erich Zulauf*, Federico Sánchez*, Sara L. Tobin†‡, Ursula Rdest* & Brian J. McCarthy*‡

* Department of Biochemistry and Biophysics, University of California, San Francisco, California 94143, USA

The Drosophila melanogaster actin genes comprise a dispersed multigene family^{1,2} of six genes, one at each of six scattered chromosomal loci (refs 1, 2 and unpublished observations). These genes encode the Drosophila actins I, II and III3,4, which can be separated in the isoelectric focusing dimension of twodimensional gels. Actins II and III have been found in all tissues, with actin III an unstable species except in adult thorax5, while actin I, the most acidic form, appears during larval myogenesis both in vivo and in vitro 3,4. Some actins therefore seem to be developmentally regulated. If individual members of a multigene family are regulated at the transcriptional level, this implies that developmental mechanisms of gene regulation can be elucidated by comparing gene family members. We report here a pattern of transcriptional activity of the D. melanogaster actin gene at the 79B chromosomal locus. Our results suggest that the 79B actin gene encodes actin I, the larval muscle-specific actin, and that actin I is synthesized initially as a precursor. The precursor co-migrates with cytoplasmic actin at the position of actin II and is subsequently acetylated to form actin I.

Because actin is a highly conserved protein⁶, the DNA sequences encoding the protein cross-react with great efficiency, both within actin gene family members of a particular organism and between different species 1.7-10, and so the gene sequences themselves cannot be used to detect the transcript of any one individual gene. We therefore isolated a specific probe from the transcribed, but non-translated 3' portion of the 79B actin gene and used it to investigate the transcriptional activity of the 79B gene at different stages of *Drosophila* development. We also used this probe to select homologous mRNA from a heterogeneous mRNA population. The message which bound to this

Fig. 1 Physical map of the actin gene at the 79B cytological locus. This 2.8-kb HindIII DNA fragment from phage λ insert DNA 11 containing the 79B actin gene was subcloned into the plasmid pBR322 as described previously 1. The locations of restriction endonuclease sites within the plasmid insert are indicated. The dashed line and arrow indicate the amino acid-encoding region of the plasmid and direction of transcription as determined by DNA sequence analysis 14. The AvaI-HindIII fragment at the 3' end of the gene delineated by the dotted line was used as the gene-specific probe for the 79B actin gene. The DNA sequence from the 3' end of the amino acid-coding region to the AvaI restriction endonuclease cleavage site at the beginning of the gene-specific probe is shown.

probe was then eluted, translated *in vitro* and the translation products electrophoresed on two-dimensional gels to distinguish between actins I, II and III.

Several clones representing the 79B actin gene were isolated from a bank of Canton S DNA cloned into phage λ by Maniatis and co-workers¹¹, using our original actin clone Kla (ref. 1) as probe. The presumptive coding region of each as identified by homology to Kla was subcloned into pBR322. The 79B cytological locus of origin¹² was established by *in situ* hybridization¹³ of a ³H-labelled cRNA probe synthesized using as template a subclone representing a region flanking the actin protein-coding

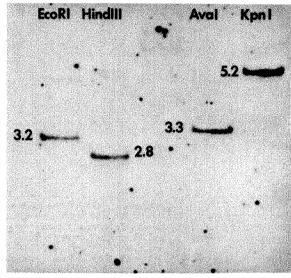

Fig. 2 Autoradiogram illustrating hybridization of the 79B gene-specific probe to genomic DNA from Canton S embryos. The 79B gene-specific probe was isolated from a preparative digest of whole plasmid DNA¹, labelled with ³²P by nick-translation ¹⁵ and hybridized to Canton S embryo DNA that had been cut with the indicated restriction endonucleases, electrophoresed in a 1% agarose gel and transferred to a nitrocellulose filter²⁵. The sizes of labelled fragments (kb) are indicated (exposure 4 days).

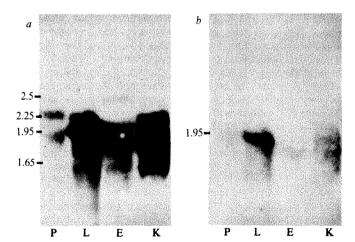

Fig. 3 Autoradiogram illustrating hybridization of coding region (a) and gene-specific (b) probes to poly(A) RNAs from embryos, larvae, pupae and Kc cells. Probes were labelled by nick-translation and hybridized to poly(A) RNAs that had been denatured, separated on a single methyl mercury-containing agarose gel and covalently bound to a diazobenzyloxymethyl paper filter and covalently bound to a diazobenzyloxymethyl paper filter and covalently from the scatting gene which contains the complete actin amino acid-coding region of that gene. This gene was one of those we have isolated from the Maniatis Canton S genome bank and is homologous to that previously described. The probe was removed by several washes with 95% formamide at 45 °C. b, Hybridization of 79B gene-specific probe to filter. The sizes of the labelled transcripts (kb) are indicated. Embryos (E); larvae (L); pupae (P); Kc cells (K).

[†] Present address: Department of Molecular Biology and Biochemistry, University of California, Irvine, California 92717, USA.

sequence¹. All 79B clones were characterized by an EcoRI restriction endonuclease cleavage site within an intervening sequence starting at amino acid 307 (data to be presented elsewhere).

Figure 1 shows a restriction endonuclease cleavage map of the 79B actin gene. The gene-specific probe is indicated and the AvaI restriction endonuclease site at which it begins has been localized by DNA sequence analysis 14 at 30 nucleotides beyond the 3' end of the amino acid coding region. We have used the fragment indicated in Fig. 1 for the experiments described here. This DNA fragment contains no amino acid-encoding nucleotides and, as shown in Fig. 2, hybridizes to only one genome DNA fragment with a molecular weight corresponding to that of the original clone fragment from which it was derived. This may be contrasted with the seven fragments labelled when a similar blot of EcoRI-digested Canton S genome DNA is hybridized to an amino acid-coding region probe 2 .

The gene-specific probe was labelled with ³²P by nick-transand hybridized to populations of poly(A)RNAs isolated from three different stages of Drosophila development and from Kc cells16 which had been fractionated on an agarose gel and transferred to diazotized paper¹⁷. Figure 3 contrasts the reaction of a coding region probe which will hybridize to all actin transcripts with the hybridization of the 79B gene-specific probe. Actin transcripts of varying lengths (1.65-2.5 kilobases (kb)) can be observed in the preparations while the 79B genespecific probe hybridizes strongly to only one RNA species (1.95 kb) from early third instar larvae and weakly to RNA from Kc cells. Because the transcripts homologous to the 79B genespecific probe constitute a significant proportion only of larval actin message, the 79B gene seems to function independently of at least some other actin genes. This experiment establishes developmental specificity of the transcriptional activity of the 79B locus.

To determine whether actins I, II or III are synthesized by the 79B actin gene, we immobilized the gene-specific probe DNA on nitrocellulose, hybridized the probe DNA to homologous poly(A) RNA from early third instar larvae, eluted the bound RNA¹⁸ and translated the RNA in vitro¹⁹. Figure 4a, b shows the translation products after separation by two-dimensional electrophoresis²⁰. Before selection of the 79B gene-specific transcripts, actins I, II and III are observed (Fig. 4a). In contrast, translation products of the RNA homologous to the 79B gene-specific probe migrate at the positions of actins I and II (Fig. 4b). These results differ from those obtained with translation

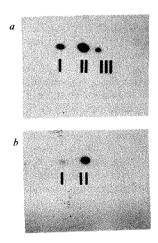

Fig. 4 Autoradiograms of two-dimensional gel electrophoresis of ³⁵S-methionine-labelled translation products of early third instar larval RNAs. a, Poly(A) RNA¹ from early third instar larvae was translated in vitro¹⁹ and the translation products electrophoresed in two dimensions²⁰. b, The same RNA was hybridized to DNA of the 79B gene-specific probe and the bound RNA eluted¹⁸. This RNA was then translated and electrophoresed simultaneously with shared buffer chambers with gel a. Actins I, II and III are indicated.

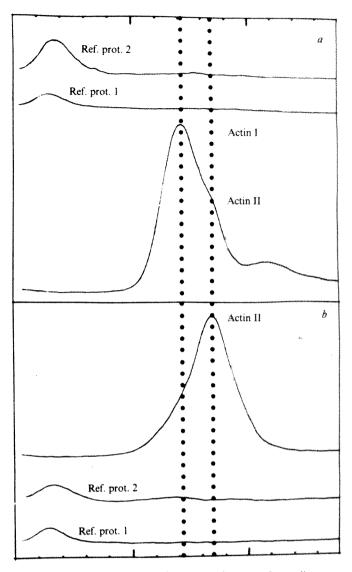

Fig. 5 Densitometer scan of an autoradiogram of two-dimensional gel electrophoresis of ³⁵S-methionine-labelled translation products with and without reagents which prevent acetylation of the *in vitro* synthesized proteins²⁴. Total RNA was isolated from early third instar larvae¹ and translated *in vitro*¹⁹. The translation products were electrophoresed simultaneously with shared buffer chambers in two dimensions²⁰ and autoradiographed. The X-ray films were scanned with a soft laser scanning densitometer (Biomed Instruments). Two reference proteins from each gel are included. a, Densitometer scan of actins and two reference proteins which were translation products of total RNA from early third instar larvae. b, Densitometer scan of actins and two reference proteins which were translated from the same RNA preparation in the presence of citrate synthase (0.88 units per 25-µlreaction solution) and oxaloacetate (1 mM) as described by Palmiter²⁴.

products (actins II and III) of RNAs selected by a cytoplasmic *Drosophila* actin gene probe². Thus, either the gene-specific probe selects more than one message or the two actins observed are related by a precursor-product relationship. We think the first hypothesis unlikely because the probe does not hybridize to other actin genes (see Fig. 2).

If the isoelectric point shift between actin II and actin I were due to post-translational processing, acetylation would seem a likely candidate for several reasons. Actin III is converted into actin II by an acetylation²¹ in Kc cells, causing a shift in isoelectric point from 5.84 to 5.77 (ref. 3). As the isoelectric points of actin I (5.70) and actin II (5.77) also differ by 0.07 pH units, acetylation of actin II could account for its conversion into actin I. The reticulocyte lysate has a ribosome-associated transacetylase²² which is capable of acetylating *Dictyostelium* actin²³.

Also, a proportion of the in vitro acetylation of proteins in the reticulocyte translation system can be suppressed by the addition of oxaloacetate and citrate synthase²⁴. Consequently, we carried out in vitro translation of total larval RNA with and without oxaloacetate and citrate synthase and separated the products by two-dimensional electrophoresis. The results of this experiment are shown in Fig. 5a, b. When acetylation is suppressed to this degree, actin I is greatly reduced, presumably because of diminished conversion of actin II into actin I. The peak of actin II is increased, presumably due to accumulation of actin II which would ordinarily have been acetylated into actin I. These results strongly suggest that actin I is synthesized as a component that initially co-migrates with acetylated cytoplasmic actin and is subsequently acetylated. The acetylation of a precursor can thus account for the characteristic isoelectric point and position on two-dimensional gels of actin I^{3,4}, and can also explain why the turnover of actin III in muscle cells is insufficient to account for the quantity of actin II observed^{3,4}. In addition, this result suggests the evolutionary conservation of mechanisms of acetylation because the rabbit acetylase is apparently able to recognize and acetylate Drosophila actins.

Thus, we believe the 79B actin gene encodes actin I, the larval muscle-specific actin, although it does not seem to be the only actin gene to do so (unpublished data). Several characteristics of the transcript of this gene are consistent with this hypothesis; for example, the stage at which the gene is active, the difference in size of the transcript from that of one of the cytoplasmic messages² and the synthesis of actin I by in vitro translation of mRNA homologous to the 79B gene-specific probe.

The 79B locus seems to be developmentally regulated independently of other *Drosophila* actin genes (Fig. 3). Differential control of actin gene expression during development may at least partly explain the multiplicity of actin genes which have been found in several eukaryotes^{7,8}. We are continuing to develop gene-specific probes for the remainder of the actin genes of *D. melanogaster* to investigate the pattern(s) of gene expression and form of actin synthesized by each. These patterns of expression will ultimately be correlated with DNA sequence information from the 5' regions of each actin gene so as to define the sequences responsible for this regulation.

We thank Dr James W. Fristrom for the gift of Drosophila embryos and larvae, and Jeanette Natzle for allowing us to use the 'Northern' blot for Fig. 3. E.Z. is a postdoctoral fellow of the Swiss NSF, F.S. and S.L.T. of the NIH, and U.R. is supported by a grant of the Deutsche Forschungsgemeinschaft. This work is supported by grants from the NIH and NSF to B.J.M. and by grants from the NIH to J. W. Fristrom.

Gene required in G₁ for commitment to cell cycle and in G₂ for control of mitosis in fission yeast

Paul Nurse & Yvonne Bissett

School of Biology, University of Sussex, Brighton BN1 9QG, UK Department of Zoology, University of Edinburgh, West Mains Road, Edinburgh EH9 3JT, UK

The control regulating commitment to the cell division cycle of eukaryotes seems to occur before the initiation of DNA replication 1-4. In the budding yeast Saccharomyces cerevisiae, this control is called start and is the earliest gene-controlled event of the cell cycle³⁻⁵. A haploid cell which has completed start is committed to cell division and unable to undergo alternative developmental fates such as conjugation. Here, we describe an analogous start control in the fission yeast Schizosaccharomyces pombe. We have tested the ability of cdc mutants blocked at various stages of the cell cycle to undergo conjugation. Only mutants of cdc 2 and cdc 10 which block during the G1 period are able to conjugate. Other mutants which block during G1, S phase, G2 or mitosis are committed to cell division and cannot conjugate. The commitment control start is located in G1, and its completion requires the gene functions of cdc 2 and 10. Completion of start occurs at the beginning of the cell cycle in rapidly growing cells, but is delayed to later in the cell cycle at slow growth rates. The cdc 2 gene function also participates in another major cell cycle control which determines the timing of mitosis⁶⁻⁸. Therefore cdc 2 is a cell cycle control gene which acts at two separate points in the cell cycle: it is required in G. for commitment to cell division and in G2 for the control of mitosis.

When dividing S. pombe cells are deprived of nitrogen, they stop proliferating, accumulate in G₁ and, if they are of appropriate mating type, undergo conjugation and sporulation^{9,10}. To determine whether conjugation is limited to a specific phase of the S. pombe cell cycle, various temperature-sensitive cdc mutants were incubated at their restrictive temperature to block cells at different places in the cell cycle, and the ability of these cells to conjugate was tested. The restrictive temperature of the cdc mutants was either 35 or 36 °C (refs 11, 12, 20), but at these temperatures conjugation in wild type was inhibited. As the highest temperature at which a reasonable level of conjugation took place was 33 °C (ref. 10), the experiment was carried out by incubating the cdc mutant cells for two generations at 36 °C to block progress through the cell cycle, followed by shifting the cells to 33 °C and mixing them with cells of opposite mating type to allow conjugation to take place. After overnight incubation the mating mix was plated out to assay the number of diploid cells formed as a consequence of conjugation (for practical details see Table 1 legend). In these conditions of temperature and medium, mutants of 11 of the 16 cdc genes known to be required for DNA replication or mitosis were blocked in their progress through the cell cycle. Mutants of the other five genes were not completely blocked and could not be used in the experiment. The levels of conjugation expressed as a percentage of a wild-type control are given in Table 1 (column 1). Only mutants of cdc 2 and 10 gave high levels of conjugation. Other mutants were <5% of the wild-type control.

Before concluding that all the cdc genes apart from cdc 2 and 10 block at cell cycle stages where conjugation is not possible, it is necessary to eliminate various other explanations for the failure of conjugation in the blocked mutants. The first possibility is that the viability of the cdc mutants is dramatically reduced after incubation at the restrictive temperature. This was not the case because the viabilities of the cdc mutants after 5 h at 36 °C and overnight at 33 °C were high, the lowest values being ~20% for cdc 24.M38 and cdc 6.23 (column 4 of Table 1). A second possibility is that the cdc mutants are partially sterile and have a reduced ability to mate even at the permissive temperature. This was not the case either, because at 25 °C all the mutants mated well, the lowest being ~30% of the wild-type control for cdc 17.K42 and cdc 25.22 (column 2 of Table 1). A third, more subtle, possibility is that the cdc mutant function is directly required in the conjugation process, and that this is the reason conjugation is prevented at the restrictive temperature (for a fuller discussion of this point see ref. 5). This possibility was tested by first accumulating the cdc mutant cells at the appropriate cell cycle stage for mating by incubation at 25 °C in nitrogen-free medium, shifting the cells to 33 °C and then mixing them with cells of opposite mating type. In these conditions, all the cdc mutants underwent conjugation, demonstrating that they were not directly involved in the conjugation process (column 3 of Table 1). Two mutants, cdc 1.7 and cdc 25.22, did have rather reduced conjugation frequencies, ~ 10 -15%, but these levels were still far greater than their conjugation frequencies at 36/33 °C.

These experiments demonstrate that mutants of cdc 17, 22, 23, 24 (involved in G_1 or S phase) and of cdc 1, 6, 13, 25, 27 (involved in G_2 or mitosis) block at stages in the cell cycle where conjugation is not possible whereas mutants of cdc 2 and 10 block at a stage where it is possible. Two different mutant alleles of cdc 2 and 10 behave similarly (Table 1), indicating that the ability to conjugate at the restrictive temperature was not due to the presence of a second mutation in the strains. The stage at which cdc 10 mutant cells become blocked is during G_1 , before the initiation of S phase^{11,12}. The situation with cdc 2 is more complex as cdc 2 mutants were previously thought to become blocked only in late G_2 just before mitosis^{8,11}. However, cdc 2

The cdc h mutant cultures were grown at 25 °C in minimal , washed and resuspended in minimal medium lacking the nitrogen source, and incubated at 25 or 36 °C. After 5 h cells were mixed with a ×10 excess of *ura* 1 *mei* 1-B102 cells¹⁰, the 25 °C culture was split and incubated at 25 °C and 33 °C, and the 36 °C culture incubated at 33 °C. After overnight incubation the mating mix was sonicated and plated onto minimal medium at 36 °C. Only complemented diploids derived from a conjugation event between the cdc h and ura 1 mei 1-B102 parents could form colonies in these conditions. All the cdc mutants were recessive to wild type. The mating type allele mei 1-B102 (also known as mat 2-Pm) was used as this allows conjugation with cells of h mating type but prevents meiosis and sporulation. Consequently a stable diploid is formed. In each batch of experiments a control ade 6 h culture was also crossed to ura 1 mei 1-B102 to determine the numbers of diploids formed from wild-type cells which were not blocked in cell cycle progress by a cdc mutation. The levels of conjugation quoted here are expressed as percentages of this wild-type control under the temperature regime used. The per cent viabilities of the cdc mutants were calculated from comparison of particle and colony counts after cultures had been incubated in minimal medium lacking the nitrogen source for 5 h at 36 °C followed by overnight incubation at 33 °C.

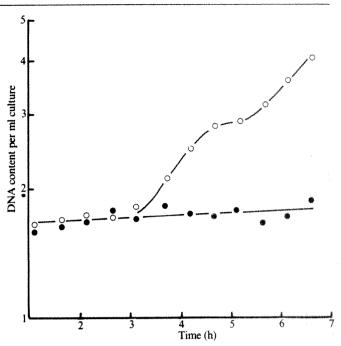

Fig. 1 cdc 2.33 h and 972 h wild-type cells were incubated in minimal medium lacking a nitrogen source at 25 °C and were re-innoculated into fresh minimal medium at 36 °C at time = 0 h. the DNA contents in the two cultures were estimated using the diphenylamine reaction Both cultures began with cells containing the G₁ content of DNA. DNA contents per ml are plotted on an arbitary log scale, and the actual DNA content per ml equivalent to 1 unit on the scale is given in parentheses following the symbol key.

○, 972 wild type (76 ng); ●, cdc 2.33 (68 ng).

mutant cells actually become blocked in G₁ as well as G₂, as is shown by the following experiment. cdc 2.33 cells were accumulated in G₁ by nitrogen starvation at 25 °C and a synchronous culture prepared by re-innoculating the cells into fresh medium at 36 °C. In these conditions wild-type cells undergo a synchronous round of DNA replication, but this does not occur in cdc 2.33 (Fig. 1). Thus, cdc is required independently for the two major events of the cell cycle, S phase and mitosis.

If cdc 2 has two cell cycle block points, it is likely that only those cells blocked at the first point in G1 are able to undergo conjugation. If this was the case it would account for the reduced conjugation of cdc 2 mutants compared with cdc 10 (Table 1, column 1), as the long G₂ period found in S. pombe would result in most cells accumulating at the second block point in late G2 where they could not conjugate. To test this, a synchronous culture of cdc 2.33 was prepared by selection of cells early in the cell cycle (mostly at the beginning of G₂), using sedimentation rate centrifugation. This culture was grown at 25 °C, and aliquots were shifted at various times during the cell cycle to 36/33 °C following the procedure described in the earlier experiments, to measure the ability of the cells to conjugate. If there is only one block point in the cell cycle, regardless of when the shift up occurred, the level of conjugation should have been the same. However, if there are two block points, one at which cells could conjugate and one at which they could not, there should have been a peak in the level of conjugation at the former block point. This second pattern was the one observed, with the mid-point of the peak occurring at the very beginning of the cell cycle coincident with cell division (Fig. 2). This is close to the timing of the G₁ period, indicating that conjugation is possible only at the G₁ block point.

We conclude that there is a start control in fission yeast which functions during the G_1 period. Before start, cells can still conjugate but after start they become committed to cell division and are unable to conjugate. Completion of start and commitment to the cell cycle requires the genes cdc 2 and 10. Rapidly growing cells complete the cdc 10 gene function very early, immediately after mitosis, but in more slowly growing cells the

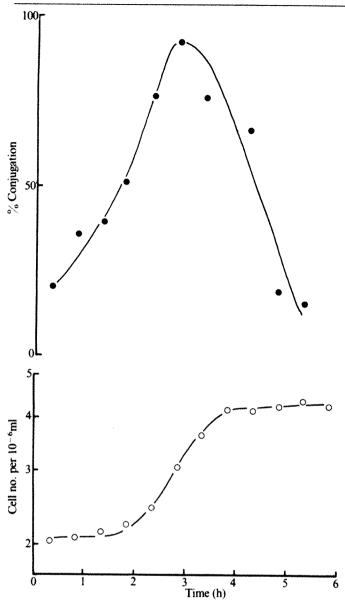

Fig. 2 A synchronous culture of cdc 2.33 h was prepared from an exponentially growing culture by sedimentation rate velocity centrifugation of the cells through a 7.5-30% lactose gradient to isolate the small cells at the beginning of the cell cycle⁶. The synchronous culture was grown in minimal medium at 25 °C and aliquots were shifted at intervals to 36 °C for 5 h in minimal medium lacking a nitrogen source, before shifting to 33 °C and mixing with ura 1 mei 1-B102. The mixing and subsequent processing were as described in Table 1 legend. Cell number was measured using a Coulter counter⁶. •, % conjugation; O, cell number per ml.

cdc 10 function is completed much later in the cell cycle¹¹⁻¹³. Thus, commitment to cell division occurs at the beginning of the cell cycle in rapidly growing cells, but is delayed to later in the cell cycle at slow growth rates. With the appropriate environmental cues these uncommitted cells can undergo an alternative developmental pathway such as conjugation. A similar situation also applies in S. cerevisiae 14

cdc 2 is unique among cell cycle genes in being required independently for two cell cycle events, start and mitosis. Together with wee 1, cdc 2 is involved in the control determining the timing of mitosis⁶⁻⁸. Therefore, cdc 2 can be considered a cell cycle control gene with regulatory functions at two control points during the cycle—start in G₁ and the timing of mitosis in G₂. Attainment of a critical cell size is required before mitosis can take place 15-17. In addition, traverse of start as marked by the completion of cdc 10 gene function¹³ or the occurrence of S phase^{6-8,18,19} also requires a critical, though different cell size.

Thus, cell size may have an important regulatory role at both cell cycle control points.

We thank Murdoch Mitchison and Peter Fantes for useful discussions during this work, Raehel McIntosh for technical assistance and the SRC for financial support.

Hydrolysis of ATP and reversible binding to F-actin by myosin heavy chains free of all light chains

Paul D. Wagner & Edward Giniger

Cardiovascular Research Institute, School of Medicine. University of California, San Francisco, San Francisco, California 94143, USA

Myosin has two 'heads' or subfragments-1 (S-1) each containing a heavy chain, a phosphorylatable or 'regulatory' light chain and another light chain which is generally referred to as being essential¹⁻³. The regulatory light chains can be removed without loss of ATPase activity3, but until now it has not been possible to remove the other class of light chain without complete loss of ATPase activity4. However, the dissociating conditions used also denature the heavy chains, and inactivation frequently precedes light-chain dissociation⁵. We now describe the use of mild dissociating conditions combined with affinity chromatography using antibodies to the alkali light chains to produce light-chain-free S-1 heavy chains. The S-1 heavy chain binds reversibly to F-actin and has 30-80% of the ATPase activities of native S-1.

Fast skeletal muscle myosin has two different but related essential light chains, alkali-1 (molecular weight $(M_r) = 20,700$) and alkali-2 $(M_r = 16,500)^6$. Two S-1 isozymes, S-1(A1) and S-1(A2), can be separated on the basis of their alkali light-chain content. These two forms of S-1 seem to have the same heavychain compositions, that is, both contain the same two Nterminal sequences⁷. In the absence of actin, S-1(A1) and S-1(A2) have the same ATPase activities. However, at low ionic strengths, the actin-activated ATPase of S-1(A2) has a higher maximal rate of ATP hydrolysis (V_{max})⁸. Using 4.7 M NH₄Cl as a dissociant, purified alkali light chains have been exchanged into S-1 or myosin without inactivation9. Similar techniques have been used to prepare hybrids which contain heavy chains from one muscle myosin and 'essential' light chains from a different muscle myosin⁹⁻¹¹. Here we have modified the exchange conditions to allow the separation of light chains from heavy chains.

Rabbit antibodies to the alkali light chains of chicken pectoralis muscle myosin were purified and coupled to CNBractivated Sepharose 4B (3 mg of antibody per ml of Sepharose) as described elsewhere 12. The immunoadsorbent column was eluted in conditions similar to those used in the exchanges, but

ATPase assays were done using a pH stat to measure the rate of H⁺ release at pH 8.0 and 25° C. Assay conditions for the EDTA-ATPase were: 2 mM EDTA, 5 mM ATP and 0.6 M KCl; for the Ca²⁺-ATPase: 10 mM Ca²⁺, 5 mM ATP and 0.6 M KCl; and for the actin-activated ATPase: 2 mM MgCl₂, 1 mM ATP and 12 or 32 mM KCl. The actin-activated ATPases were analysed using the following equation ¹⁸: $v = V_{\text{max}} \left[\frac{\text{actin}}{K_{\text{app}}} + \frac{\text{actin}}{K_{\text{app}}} \right] = \frac{V_{\text{max}}}{V_{\text{max}}} \left[\frac{V_{\text{max}}}{V_{\text{max}}} \right] = \frac{V_{\text{max}}}{V_{\text$

* S-1(A2) was diluted to 0.25 mg ml⁻¹ with 4.6 M NH₄Cl, 2 mM ATP, 2 mM DTT, 2 mM EDTA and 0.10 M imidazole, pH 7.0 at 4° C. After 1 h, MgCl₂ was added to 5 mM and the S-1(A2) dialysed as described for the light-chain-depleted samples.

† S-1 heavy-chain samples were prepared as described in Fig. 1 legend. The amount of alkali-2 light chain in the samples was determined by densitometry of Coomassie brilliant blue-stained SDS-polyacrylamide gels. The two different S-1 heavy-chain preparations shown indicate the variability in the EDTA-ATPase activities.

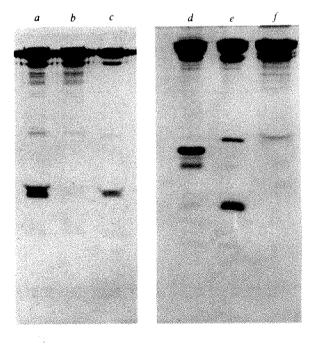

2 mM ATP was added to stabilize the heavy chains during the 1-h isolation procedure and $MgCl_2$ was added to 5 mM before the removal of the NH_4Cl .

When S-1(A2) was applied to the column, the protein eluting in NH₄Cl contained 85–90% S-1 heavy chain and 10–15% S-1(A2) (Fig. 1). (The phosphorylatable light chains were removed during the digestion of myosin to S-1.) After removing the NH₄Cl, the light-chain-depleted samples had 45–80% of the EDTA-ATPase and ~40% of the Ca²⁺-ATPase of native S-1(A2) (see Table 1). This decrease in ATPase activity may be due in part to the NH₄Cl treatment. In the exchange experiments, where the S-1 was 2.3 mg ml⁻¹, there was only a 10–15% loss in activity. However, when S-1 was left in NH₄Cl for 1 h at

0.25 mg ml⁻¹, equivalent to the S-1 heavy-chain concentration which elutes from the immunoadsorbent column, there was a 25-40% decrease in ATPase activities (Table 1).

When an equal mixture of S-1(A2) and S-1(A1) was applied to the immunoadsorbent column in the same conditions as for Fig. 1, the eluate contained no alkali-2 light chains and half the level of alkali-1 present in the applied S-1. This sample had 73% of the EDTA-ATPase and 45% of the Ca²⁺-ATPase of native S-1. There are two obvious explanations for the preferential removal of the alkali-2 light chain by the immunoadsorbent column: either these particular antibodies interact more strongly with the alkali-2 than with the alkali-1 light chains, or the latter bind more tightly to the S-1 heavy chains than do alkali-2

Fig. 1 SDS-polyacrylamide gel electrophoresis of S-1 heavychain preparations. S-1 was prepared by an α -chymotryptic digestion of chicken pectoralis myosin and fractionated into S-1(A1) and S-1(A2)⁸, S-1(A2) (5.0 mg) was incubated for 5 min at 4° C in 1 ml of 4.7 M NH₄Cl, 5 mM ATP, 2 mM EDTA, 2 mM dithiothreitol (DTT) and 0.10 M imidazole, pH 7.0, and then loaded on to a 1.6×5 cm immunoadsorbent column (containing antibodies specific for alkali light chains) equilibrated in 4.6 M NH₄Cl, 2 mM ATP, 2 mM DTT, 2 mM EDTA and 0.10 M imidazole, pH 7.0. The column was eluted with this equilibration buffer at 20 ml h and 2.5-ml fractions were collected. The two peak fractions, 0.2 to 0.3 mg ml⁻¹, were pooled and MgCl₂ added to a concentration of , were pooled and MgCl2 added to a concentration of 5 mM; 4 ml were dialysed against 0.2 M KCl, 2×10⁻⁴ M DTT and 5 mM imidazole, pH 7.0 at 4° C, for use in the ATPase assays, and 1 ml was dialysed against 20 mM NaCl, 2×10^{-4} M DTT and 5 mM imidazole, pH 7.0 at 4°C, for SDS-polyacrylamide gel electrophoresis. The immunoadsorbent column was regenerated by washing rapidly with 4 M guanidine-HCl. The capacity of the column decreased with use; after six runs only two-thirds as much S-1 could be applied. An $A_{280}^{1\%}$ of 7.5 and a molecular weight of 115,000 was used for S-1(A2) and for S-1 heavy chain these values were estimated to be 8.6 and 95,000. SDS-polyacrylamide gel electrophoresis was carried out as described by Laemmli' 50 μg of S-1(A2); b, 50 μg S-1 heavy chain, eluted from the immunoadsorbent column in NH₄Cl; c, 25 μg of S-1(A2); d, 50 μg S-1(A1); e, 50 μ g S-1(A2) and f, 50 μ g S-1 heavy chain as in b, except that it was further purified with the immunoadsorbent column equilibrated in 0.2 M KCl. S-1 heavy chain containing 20% contaminating S-1(A2), 11 ml at 0.25 mg ml⁻¹, was concentrated by ultrafiltration to 2 ml at 1.4 mg ml⁻¹ and applied to the immunoadsorbent column equilibrated in 0.2 M KCl, 2×10 DTT and 5 mM imidazole, pH 7.0 at 4° C. S-1(A2) bound to the column and pure S-1 heavy chain passed through.

light chains. The latter explanation is supported by the observation that the alkali-1 light chain exchanges into myosin more easily that alkali-2 light chain 10. As the alkali-2 light chain is more easily removed from S-1 than alkali-1 light chain, in the rest of the experiments described here, the S-1 and heavy chains were prepared from S-1(A2).

The actin-activated ATPases of both S-1 and S-1 heavy chain have hyperbolic dependences on actin concentration (Fig. 2). In preparation A of Table 1, after correcting for residual S-1(A2), the V_{max} of S-1 heavy chain was 49% that of native S-1(A2) and 67% that of NH₄Cl-treated S-1(A2). In these assay conditions, the V_{max} of S-1(A1) is about half that of S-1(A2), but when the ionic strength is increased to 0.04 M, the $V_{\rm max}$ of S-1(A1) increases to that of S-1(A2)¹³. Preparation B of Table 1 shows the effect of ionic strength on the actin-activated ATPase of the S-1 heavy chain. Although the recovery of actin-activated ATPase was lower than in preparation A, the actin-activated ATPase activities were still much higher than could be accounted for by residual S-1(A2). The $V_{\rm max}$ of the S-1 heavy chain did not increase significantly when the ionic strength was increased. At both ionic strengths, the K_{app} of the S-1 heavy chain was between those of S-1(A2) and S-1(A1).

Further purification of the heavy chains was achieved by removing residual S-1(A2) on the immunoadsorbent column in the absence of NH₄Cl. No alkali-2 light chain was detectable on SDS-polyacrylamide gels (see Fig. 1). The EDTA-, Ca²⁺- and actin-activated ATPases of pure S-1 heavy chain were all 30% of those of native S-1(A2). The decreases in activities, most noticeable in the EDTA-ATPase, probably reflect the instability of the heavy chain during the isolation procedures.

To check that the S-1 heavy chains did not contain fragments of the alkali light chains (produced by proteolysis during the isolation procedures) which were not visible on Laemmli-type SDS gels¹⁷, the lysines of an S-1 heavy-chain sample were modified in urea with ³H-formaldehyde and NaCNBH₃ (ref. 14). The sample was run on an SDS-urea gel capable of resolving small peptides¹⁵. There were no counts in the area of small peptides which could be attributed to digestion products of the alkali light chains nor were any bands detectable by Coomassie blue staining.

The binding of the S-1 heavy chain to F-actin was examined by ultracentrifugation (see Table 2). Centrifugation in the absence of actin showed a slight aggregation of the S-1 heavy chains. (Other experiments also showed that the S-1 heavy chains tend to aggregate more readily than does S-1.) After correcting for aggregation, approximately the same fractions of S-1 heavy chain and S-1(A2) bound to F-actin in the absence of

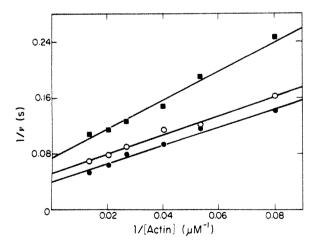

Fig. 2 Actin-activated ATPases. Assays were performed as described in Table 1 legend; v is the observed rate of ATP hydrolysis by S-1 in the presence of actin, minus that of S-1 alone. •, S-1(A2); O, NH₄Cl-treated S-1(A2); and **II**, S-1 heavy chain containing 10% S-1(A2).

Table 2 Actin binding of S-1(A2) and S-1 heavy chain preparations

	Fraction bound		
	-ATP	+ATP	
S-1(A2)	0.91 (0.02)	0.09 (0.03)	
NH ₄ Cl-treated S-1(A2)	0.82 (0.08)	0.05 (0.03)	
S-1 heavy chain (10-15% S-1(A2))	0.82 (0.06)	0.17 (0.09)	

S-1 heavy chain or S-1(A2) (1 μ M) was mixed with 36 μ M F-actin in 0.1 M KCl, 2 mM MgCl₂, 10⁻⁴ M DTT and 5 mM imidazole, pH 7.0 at 4° C. Some samples also contained 1.0 mM ATP. After centrifuging the samples at 150,000g for 30 min, the supernatants were carefully removed and aliquots electrophoresed on SDS-polyacrylamide gels. The gels were stained with Coomassie brilliant blue and the intensity of the heavy-chain bands determined using a scanning gel densitometer. When centrifuged in the absence of actin, 80% of the S-1 heavy chain and 90% of the S-1(A2) and the NH₄Cl-treated S-1(A2) remained in the supernatant. These values were used as references for determining the fraction of S-1 bound to F-actin. Values are the mean (±s.d.) of three different S-1 heavy-chain preparations

ATP, but a lower fraction of S-1 heavy chain was released by ATP.

These results show that the alkali light chains are not essential for either actin binding or ATP hydrolysis, and that the ATP and actin binding sites are located on the myosin heavy chains. However, the alkali light chains may stabilize the myosin conformation, as the heavy-chain preparations seem to be unstable. It has been reported that the isolated heavy chain of the nonfilamentous Acanthamoeba myosin 1B is fully active 16. As this myosin has many unique properties, it was not possible to extrapolate this observation to other myosins. However, as fast skeletal muscle myosin is a 'typical' myosin, it is likely that the ATP and actin binding sites of other myosins will also reside on the heavy chains.

This study was supported by USPHS Program Project Grant HL-16683 and by NSF grant PCM-75-22698. We thank Drs Manuel F. Morales and Alan G. Weeds for critical reading of the manuscript.

Erratum

In the letter 'Lamellar-zonal bone with zones and annuli in the pelvis of a sauropod dinosaur' by R. E. H. Reid, Nature 292, 49-51 (1981), the sentence beginning on the first line of page 51 should read 'Some material in the literature cited' could also be interpreted differently, for example if bone figured by Seitz (Figs 53, 54 of ref. 14) from the theropod Allosaurus is thought to show lamellar-zonal structure'.

Bird Migration in Africa

Movement Between Six Continents Kai Curry-Lindahl

October/November 1981 Volume 1: c. xvi+444pp., £41.40 (UK only)/\$99.50 0.12.200101.X Volume 2: c. xvi+208pp., £26.60 (UK only)/\$49.50 0.12.200102.8

This book describes bird movements all over Africa and discusses the factors behind them. Issues covered include the response of various habitats to the tremendous seasonal increase in the number of inhabitants, the reaction of native birds to the competition for feed, and interspecific relations between Eurasian birds and African vertebrates. The study examines the ecogeography, behaviour, evolution and ecology of birds in Africa, and supplies lists of intercontinental migrants and a timetable of their movements.

Colloid Science: A Series of Monographs

Zeta Potential in Colloid Science

August/September 1981, c. 400pp., £35.00 (UK only)/\$84.00 0.12.361960.2

The book begins with a review of the theory of the electrical double layer and electrokinetics, including a unified treatment of the behaviour of liquids in narrow capillaries and porous media. Various methods for measuring the zeta potential (electroosmosis, streaming potential, electrophoresis and sedimentation potential) are described, before a consideration of the interpretation of the zeta potential. The final chapters explore the application of the zeta potential to studies of adsorption of simple ions, hydrolysable ions, surfactants and polymers and of coagulation, flotation, sedimentation and rheology.

VLSI 81

Very Large Scale Integration edited by John P. Gray

July/August 1980, xiv + 364pp., £15.00 (UK only)/\$36.00 0.12.296860.3

This book contains the papers delivered at the Edinburgh International Conference, VLSI 81, the first meeting to be devoted exclusively to this subject. The multi-disciplinary nature of the field of very large scale integration is reflected in the organization of this book which covers the application of discrete mathematics to VLSI systems, novel architectures, design methodologies and tools, applications of VLSI systems and the design of circuits. It will be invaluable to professional engineers, research workers and postgraduate students in both hardware and

Languages and Architectures for Image Processing

edited by M.J.B. Duff and S. Levialdi

July/August 1981, c. 300pp., £16.40 (UK only)/\$39.50 0.12.223320.4

The book brings together current ideas on the interaction between special computer archietecture, developed for the manipulation of pictorial data, and the resulting demands on high-level language design. Problems associated with architecture include the choice of processors, the advantages of SIMD or SIMD/MIMD machines, the quantification of speed-up factors in terms of numbers of processors, clock-cycle and memory independently of data or computational algorithms. Coverage of the language problem includes discussion of the choice of language, the impact of ALGOL and PASCAL on image processing and computer science in general, and other related areas.

Meso-scale Atmospheric Circulations

B.W. Atkinson

July/August 1981, xviii + 494pp., £32.40 (UK only)/\$78.00 0.12.065960.3

Meso-scale Atmospheric Circulations is divided into three sections. An introductory chapter discusses the notion of the meso-scale. Section two is concerned with topographically induced circulations. These systems can be either thermally initiated (for example, sea breezes resulting from thermal differences between land and sea) or mechanically initiated (lee waves). The third section comprises four chapters on free atmosphere circulations, both convective and non-convective. All the chapters have similar structures circulation, coverage of observed structure, both analytical and numerical theoretical studies and, where available, hardware experiments.

Annual Reports on NMR Spectroscopy

Volume 11A edited by G.A. Webb

May 1981, x + 282pp., £35,00/\$84,00 0,12,505311,8

The diverse choice of topics covered by Volume 11A reflect the areas of molecular science critically dependent upon NMR investigations. The review on amino acids, peptides and proteins provides a current account of an area previously covered in Volume 6B of this series. Biologically important areas of research are also considered in the chapter on calcium and magnesium NMR in chemistry and biology. The remaining three reports in Volume 11A deal with material which, although previously considered inter alia, is given specific coverage for the first time in this

Mathematics Tomorrow

Editor: L. A. Steen

1981. 14 figures. VI, 250 pages. Cloth DM 39,—; approx. US\$18.60 ISBN 3-540-90564-2 Price is subject to change without notice

Contents: Introduction. - What Is Mathematics?: R. Halmos: Applied Mathematics Is Bad Mathematics. J. Spanier: Solving Equations Is Not Solving Problems. J.P. King: The Unexpected Art of Mathematics. A. Tucker: Redefining the Mathematics Major. T. Poston: Purity in Applications. W.F. Lucas: Growth and New Intuitions: Can We Meet the Chalenge? - Teaching and Learning Mathematics: P. Hilton: Avoiding Math Avoidance. A. Lax, G. Groat: Learning Mathematics, A. Shenitzer: Teaching Mathematics. H.M Edwards: Read the Masters! N. Koblitz: Mathematics as Propaganda. W. Kaufmann-Bühler, A. Peters, K. Peters: Mathematicians Love Books. - D.J. Albers: A Faculty in Limbo. G.M. Miller: Junior's All Grown Up Now. E.P. Miles, Jr.: NSF Support for Mathematics Education. - Issues of Equality: E.L. Poiani: The Real Energy Crisis. A. T. Schafer: Women and Mathematics. M. Boykan Pour-El: Spatial Separation in Family Life: A Mathematician's Choice. - Mathematics for Tomorrow: R.L. Finney: Applications of Undergraduate Mathematics. A. Ralston: The Decline of Calculus -The Rise of Discrete Mathematics. P.T. Boggs: Mathematical Software: How to Sell Mathematics. H. Rogers, Jr.: Physics and Mathematics. T. Robertson, R.V. Hoggs: Readin', "Ritin", and Statistics. M. Thompson: Mathematization in the Sciences.

This volume is an exploration into the future of mathematics research and mathematics education. Its 24 articles present predictions and opinions ranging from the basic question, "What is mathematics?" to mathematics for tomorrow, teaching and learning mathematics, and issues of equality. All the contributors are experienced teachers and scholars who reflect the diversity within the mathematical community.

BOOK REVIEWS

The case for unilateral disarmament

Hedley Bull

ROBERT Neild, a Professor of Economics at Cambridge and the first Director of the Stockholm International Peace Research Institute, has written a clear-headed and honest little book which will indeed help people to make up their minds about the bomb, even where (like myself) they are not able to accept his conclusions.

In Britain the debate about nuclear weapons policy, dormant throughout the late 1960s and 1970s, has been revived by the recent decisions of the government to purchase the *Trident* missile from the United States and to accept the deployment of United States cruise missiles in Britain. It is to this debate about British policy that Neild seeks to contribute. Does Britain need its own nuclear weapons? And is Britain's security more strengthened than it is endangered by the hosting of United States nuclear bases? To both questions his answers are firmly negative.

Neild holds that while the Soviet Union has developed a "beastly political system" (p.9) and engages in adventurism in the Third World, it does not present a significant military threat in Europe, where its policy is basically defensive. American nuclear weapons deployed in Western Europe, he thinks, would confer positive benefits on the latter only if it could be assumed that the United States is a "reluctant ally" that does not perceive its interests to lie in defending Western Europe. In fact, according to Neild, the United States can be relied upon to defend its investments and world role in Europe, whether or not it has nuclear weapons deployed there that will draw it into any conflict.

The presence of nuclear weapons on British soil, whether British or American, adds to the risk that Britain will be subject to nuclear attack, a danger which official policy is reluctant to acknowledge. As Neild says:

In any nuclear conflict between the United States and the Soviet Union, Britain runs the risk of being the victim of a pre-emptive strike or accident. This is what happens to aircraft carriers [p.18].

Britain's nuclear deterrent force, Neild thinks, expresses

the folly of a declining power which seeks influence on the one hand by ingratiating itself with the United States and becoming dependent on her and, on the other hand, by buying and maintaining nuclear symbols of independence

How to Make Up Your Mind About the Bomb. By Robert Neild. Pp.144. ISBN 0-233-9382-6. (André Deutsch: 1981.) Pbk £2.95.

from the United States, symbols for which it has no use since it does not seek to be independent [pp.99–100].

United States assistance to the British nuclear weapons programme, as Neild notes, has had two conditions: that British nuclear forces be assigned to Nato, and that Britain continues to provide the United States with nuclear bases and other military facilities. Britain's role as an American military base — a role that has been played continuously since the stationing of American bombers in connection with the Berlin Blockade in 1948 — is thus in part made necessary by the British nuclear weapons programme.

The network of American military bases in Britain is now vast (Neild cites a study that lists 103 "bases and facilities"). There has been extraordinarily great governmental secrecy, and extraordinarily little public debate, about their nature and implications. And it is clear that such control as Britain exercises over the use of them, including that of the nuclear-armed bombers now based in Britain, is purely political and informal in nature; nor will the nuclear-armed cruise missiles to be deployed in the next few years be subject to any "double key" system that will give Britain a share in their technical control, such as it has over Nato tactical nuclear weapons deployed on the Continent. This is the measure of the change that has taken place in Anglo-American relations since the Quebec Agreement of 1943, when each country undertook not to use nuclear weapons against any third party without the consent of the other.

Neild is right to insist that it is important to stand back from detailed strategic analysis and ask where the nuclear arms race is going. He is right also to see new dangers in the collapse of super-power arms control negotiations, the drift away from "simple deterrence" towards nuclear war-fighting in strategic doctrine and the tendency to substitute considerations of the balance of nuclear arms between the super powers for considerations of mutual nuclear deterrence. He has performed a service in calling for public debate about US military bases in Britain; many who do not support Neild's view that these should

be removed in toto will nevertheless feel, as I do, that given the present direction of United States foreign policy, Britain should be seeking to disengage from any close identification with it, and especially to assert positive control over the use of American nuclear weapons based in Britain.

But, like many rational men of science, Robert Neild does not recognize the part that is necessarily played in international relations by power, including military power. If it is true, as I expect it is, that Soviet leaders harbour no aggressive intentions towards Western Europe, it is also true that the balance of military power created by Nato forms part of the context in which Soviet intentions have taken shape. If the balance were replaced by a Soviet military preponderance in Europe, Soviet leaders would be likely to develop different intentions, if not to invade Western Europe, then at least to dominate it. "Finlandization", which Neild dismisses as a bogey, seems to me to be a very possible consequence of a lowering of the guard by the Western powers, even if the analogy with Finland is an inexact one. Similarly, if the Soviet military position in Eastern Europe were to weaken, pressures would be likely to develop in the Western world to adopt a "forward policy" of promoting change in those countries.

Neild, it is true, does not call for Britain's exit from Nato or for the withdrawal of British forces from Germany; rather, he wants Britain to adopt a "French" policy of national self-reliance in defence, but continued participation in the alliance, except that Britain, unlike France, would be without its own nuclear weapons. Neild, moreover, clearly thinks that Western Europe, even after it had expelled American nuclear weapons, could still look to the United States for military support. He does not consider whether it is morally justifiable for Western European nations to ask the American people to accept on their behalf the risks of having nuclear weapons on American soil, while refusing to accept these risks themselves.

While Britain and other West European countries at present need to distance themselves from an apparently reckless American foreign policy, they are still in danger of being dominated by the Soviet Union if a balance of power in Europe is not maintained. The long-run objective, for Western Europe, should be to create a military counterpoise to the Soviet Union

from its own resources, independently of the United States. But this requires a nuclear deterrent force or forces controlled by West Europeans themselves, for which the British and French nuclear forces now provide a basis, as is today increasingly recognized elsewhere in Western Europe (the West German government, for example, has officially welcomed the British decision to deploy *Trident*). And in the short run there can be no balance in Europe without the commitment of American nuclear forces, for which some price will have to be paid and some risks accepted.

Hedley Bull is Montague Burton Professor of International Relations at Oxford University, and was formerly a Director of the Arms Control and Disarmament Research Unit in the British Foreign Office.

Environmental chemistry: a mixed reaction

Peter S. Liss

The Handbook of Environmental Chemistry. Edited by O. Hutzinger. Three volumes of two parts. Vol.1A The Natural Environment and the Biogeochemical Cycles pp.258, ISBN 3-540-09688-4. Vol.2A Reactions and Processes pp.307, ISBN 3-540-09689-2. Vol. 3A Anthropogenic Compounds pp.274, ISBN 3-540-09690-6. (Springer-Verlag: 1980.) Vol.1A DM98, \$57.70; Vol.2A DM126, \$74.40; Vol.3A DM98, \$57.70.

THESE three volumes are the first part of what we are told in the preface will be a multi-part venture. Part Bs for all the present volumes are promised shortly, with further parts to be published at some later date. Readers are even asked for their suggestions as to what future books might contain! Thus we appear to be at the start of what could become a major exercise in environmental chemistry publishing. At this early stage perhaps it is timely to examine both the achievements of what is now published and see what guidance it gives for future projects of this sort.

Each of the present volumes contains between nine and thirteen chapters, each by different authors. Generally they seem to be aimed at an audience at post-graduate level. The whole is edited by O. Hutzinger who is in the Laboratory of Environmental and Toxicological Chemistry at the University of Amsterdam. He has clearly put in an enormous amount of work to get the venture started and presumably continues to labour mightily on future volumes. Although editorial supervision is obviously important for a worthwhile outcome, the editor is, as always in a project of this kind, almost totally at the mercy of the people who are writing the individual articles. In spite of the fact that the authors are generally well known in their subject areas, the final result here is a series of chapters of very uneven content and quality. Some authors have done a really excellent job in summarizing their allotted topics; conversely, several chapters appear to do considerable injustice to the sub-branch of environmental chemistry which they are supposed to cover. This patchiness seriously limits the value of the whole venture. Presumably, the whole purpose of a handbook is that it can always

be relied on to give the sort of information and understanding one requires. If this reliability is lost by some contributions being sub-standard, then one might as well go back to using a collection of textbooks and journal articles covering more restricted parts of the topic.

Since only Part As are currently available, it is not possible to comment at this stage on the comprehensiveness of the Handbook or on problems of overlap or underlap between chapters. The arrangement into three volumes is done in a rather interesting way. Volume 1 contains chapters on the hydrosphere, atmosphere. oceans and soils as well as contributions on aspects of biogeochemical cycling. In this last group the article by P. J. Craig, "Metal Cycles and Biological Methylation", deserves special mention since it is a most informative and well balanced appraisal of the topic, particularly with respect to the routes and importance of methylation

The second volume is concerned with reactions and processes which transport and modify substances in the environment.

Volume 3 contains nine chapters, each on a particular man-made chemical (or group of chemicals) or natural substance whose behaviour is being affected by anthropogenic activities. The list of chemicals covered so far is plainly far from complete. This treatment by individual substance is perhaps how one might have expected the whole *Handbook* to have been organized. The editor is surely right in adopting the approach of establishing the basic principles of the subject in Vols 1 and 2 before proceeding to a detailed examination of individual chemicals.

As to the future of the *Handbook* the message is clear – vigilance in choice of authors is paramount. Although articles must obviously be written by experts in their subject area, it is more important that they should be prepared to make the effort to do justice to their topic rather than be well known in the field.

Peter S. Liss is Reader in the School of Environmental Sciences, University of East Anglia, and Scientific Adviser in the Environmental Studies Section at CEGB Headquarters.

Immunity in fertility

W. D. Billington

Immunological Aspects of Reproduction and Fertility Control. Edited by J. P. Hearn. Pp.253. ISBN 0-85200-265-3/ 0-8391-4143-2. (MTP/University Park Press: 1980.) £19.95, \$44.50.

WHILE reproductive immunology has undoubtedly come of age as a discipline in its own right, it still bears the scars of its rather uncontrolled upbringing in the hands of enthusiastic but sometimes less than rigorous investigators of a wide range of backgrounds. From the resulting morass of scattered, uneven, occasionally confusing, frequently conflicting data, it is now time to extract the relevant and scientifically sound and to reject the remainder. Reviews in this field must therefore be selective, highly critical and, most emphatically, not merely exhaustive catalogues of information. This volume of ten reviews meets this requirement only in part, with almost the full range of possibilities from the truly excellent, through the generally acceptable, to the frankly deplorable. Readers familiar with the field as a whole will hopefully readily discern these categories but the newcomer will require some guidance.

The coverage of the book is wide, with many, but not all, of the immunological aspects of reproduction and fertility control included. It is really two books in one, with the first section largely examining the maternal-foetal relationships in pregnancy and the disorders and diseases, in particular infertility and pre-eclampsia. which may result from disturbances in the normal system, and the second section exploring the possible avenues leading to the production of contraceptive vaccines based upon reproductively unique antigens. The chapters are very variable in length and approach, some presenting reviews of a general topic and others structured around more specific interests and personal data. The philosophy that an understanding of normal reproductive mechanisms will illuminate both pathological events and the means of intervention, as well as vice versa, is here given reasonable substance, and there are many encouraging signs of advance in this fascinating field.

However, this is not to say that many of the major problems do not remain to be solved. Despite considerable endeavour it is still not known by what means the foetus, or more precisely the placenta, avoids rejection as an intra-uterine allograft, whether simply by failing to display appropriate target antigens or by complex mechanisms involving one or more of a diverse range of maternal cellular and humoral immunoregulatory factors. There is conclusive evidence for a primary immunological causation in very few clinical disorders of reproduction. An

acceptable form of contraceptive vaccine is also still awaited, since the most advanced contender, the placental protein hormone chorionic gonadotrophin (hCG), has demonstrated the fundamental difficulty of this approach: that of achieving effective levels of non-cross-reacting, highaffinity antibody in individuals of varied immune responsiveness with preparations of such low immunogenicity as to require the use of potentiating carrier agents and undesirable adjuvants, to say nothing of the possible side-effects. It is questionable whether three entire chapters should have been devoted to this specific molecule, although they certainly highlight the hopes and fears of those working in this important area, illustrated also by two further chapters giving consideration to the potential use of a hypothalamic releasing hormone and antigens of the zona

antigens of relevance in this context should have been relegated to the depths of the lengthy review by Jones on male and female infertility.

This book deserves to be read because it is a fair reflection of the current state of the art, warts and all. But if your time or interest is limited then my advice is to read only the conclusions to each chapter and then go on to digest in full those by Cooper, on immunological relationships between mother and conceptus, and by Redman, on immunological aspects of pre-eclampsia. Both show how it is possible to produce a balanced, critical analysis out of a confusion of data and thereby firmly point the way forward to the required goals. Future reviewers please note.

A Devonian view of vertebrate evolution

Alec Panchen

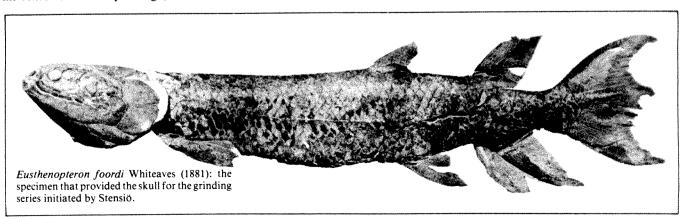

Basic Structure and Evolution of Vertebrates. By Erik Jarvik. Vol.1 pp.575, ISBN 0-12-380801-4; Vol.2 pp. 337, ISBN 0-12-380802-2. (Academic: 1981.) Vol. 1 £41, \$94.50; Vol. 2 £24.40, \$56.50.

In 1958 one of the recipients of the Linnean Society's Darwin-Wallace centenary medal was Professor E.A. Stensiö, who was honoured principally for his contribution to techniques of fossil preparation. His most important contribution was the technique of serial grinding in which specimens (particularly fossil skulls) are ground away to expose a minutely controlled series of sectional views. No specimen then remains, but a series of drawings and photographs are used to make large-scale, wax-plate reconstructions.

Stensiö may be regarded as the founder of the "Stockholm School" of vertebrate palaeontologists. Professor Jarvik, author of this two-volume work, is his former student and scientific heir, and was, until his retirement a few years ago, Stensio's successor in the Chair of Palaeozoology at the Natural History Museum in Stockholm. Thus these volumes record the meticulously detailed comparative anatomy and palaeontology, with numerous, detailed and beautiful line drawings, which characterize the Stockholm School. Unhappily, however, another characteristic feature of the work of Stensiö, Jarvik and their coworkers is very much to the fore: this is due to their isolation, in matters of principle, theory and interpretation, from colleagues elsewhere in the world and particularly from English-speaking palaeontologists. Thus anyone who expects a balanced review of important problems in vertebrate evolution, with views opposed to Jarvik's given due weight, will be disappointed. Not for him is Sir Karl Popper's dictum that the good philosopher or scientist should put his opponent's case in the most convincing manner before proceeding to criticize it.

Following an introduction Jarvik's first two chapters, amounting to 184 pages, are devoted to an uncompromisingly detailed account of the anatomy of two fish, the primitive extant form Amia and the Devonian fossil Eusthenopteron. The account of Amia is confined to the skeleton and to those features of the "soft anatomy" which can reasonably be restored in a well-preserved fossil skull. The account of Eusthenopteron is equally detailed with the "soft anatomy" restored by comparison with Amia and other vertebrates. Eusthenopteron has for many vears been accorded great importance by students of vertebrate phylogeny as the best known representative of a group of fishes standing close to the ancestry of land vertebrates. Jarvik's preoccupation with it has endured throughout his research career, largely as the result of studying ones superb skull specimen from a grinding series initiated by Stensiö.

The rest of the first volume is devoted to a review of early fossil vertebrates. Apart from details from living forms and occasional fossils used solely for comparison, none is of later than Devonian age, i.e. less than about 350 million years old. One practical and one theoretical consideration seem to have conditioned this choice: the first is that Jarvik and his present Stockholm colleagues have done little or no work on post-Devonian fossil vertebrates; the second is Jarvik's oftenrepeated view that all of the most important events in vertebrate evolution were over by the end of the Devonian, so that (with some exaggeration) Homo sapiens might be regarded as a aberrant Eusthenopteron-like fish! Specialists will find much to admire and also much to disagree with in the details of this review section: Jarvik's heterodox view that both the Dipnoi (lungfish) and the extinct acanthodians are more closely related to sharks than to bony fish will provoke many, as will the views (derived from Stensiö) on the nature of the relationship of early jawless vertebrates to extant cyclostomes. However, perhaps of more general interest is Jarvik's partial fulfilment of a frequently-expressed hope of his colleagues world-wide. Jarvik's department has on loan from the Danish Government an enormous mass of material of the world's earliest known amphibia from the Devonian of East Greenland. The original specimens, deposited in Stockholm over 50 years ago, were

Industrial Biotechnology 5th Floor 31/33 High Holborn London WC1V 6BD 01-404 0496. Telex 912881 CW UK TXE (Micro) reviewed by the late G. Säve-Söderbergh in 1932 and since then scraps of information, mostly in the form of annotated drawings, have been released by Jarvik. This review section of his new book yields a few more crumbs in the form of figures and brief descriptions of the limbs and limb girdles, but people will still ask when the definitive monograph on these so-called ichthyostegids is to appear: 50 years is a long time, even in vertebrate palaeontology.

While Jarvik's first volume does deal to some extent with (often heterodox) theories of relationship between groups of fishes, it consists mostly of comparative anatomy and taxonomy. However, the second, shorter, volume is concerned principally with theory. It is divided into four major sections: "Basic structure and composition of vertebrate head" (sic), "The origin of the paired extremities", "The origin of tetrapods" and "Recapitulation and comment".

At first glance the opening section appears to be a very old-fashioned treatise on the embryology and anatomy of the skull and associated structures, but there is more to it than that. Jarvik attempts to demonstrate that a much larger part of the cranial anatomy of vertebrates than is normally accepted is not just segmented ("metameric") but actually formed of modified vertebrae — a reversion to the theories of the German Naturphilosophen of the early nineteenth century and particularly those of the poet Goethe. In this attempt Jarvik relies heavily on the work of his colleague H.C. Bjerring.

The following section is something of a pleasant surprise in that it opens with a brief but adequate consideration of rival theories of the origin of the paired fins of fishes. Ironically, Jarvik's views on this subject probably represent his most successful challenge to orthodoxy. However, they are followed by a treatment of the origin of the limbs of tetrapods which is strongly coloured by Jarvik's best known and most controversial theory. This is that one group of tetrapods, the Urodela (newts and salamanders) evolved from a different known group of now-fossil fish than did all other tetrapods (the remaining amphibia, reptiles, birds and mammals). Throughout both volumes this theory keeps popping up — sometimes it is assumed in the interpretation of other theories or data, at other times evidence is cited to support it, occasionally with complete circularity of argument. Within the penultimate section of the second volume it is developed in full. It arose originally from Jarvik's study of the snout of Eusthenopteron in which he documented a series of anatomical resemblances to the snout of frogs. He then claimed a second series of resemblances connecting members of another group of Devonian fish with the urodeles. Subsequently he has elaborated the comparison, seeking confirmation in other anatomical details. Many workers now

consider the theory to have been refuted by the study of amphibian snouts made by a South African, J.D. Jurgens, but Jarvik does not adequately discuss Jurgens's case.

As a bonus, Jarvik prefaces his discussion of tetrapod origin by a new theory of the mammalian ear in which he derives the three middle-ear ossicles of mammals from the hyoid arch of Eusthenopteron and, in rejecting the orthodox homologies, established over 140 years ago, virtually ignores the evidence from the rich source of fossil "mammallike reptiles".

The final section of the book opens with a chapter on general principles and methods, but does not really address the problem of the irreconcilable methodological differences between the author and his colleagues outside Stockholm. To Jarvik, the correct method of reconstructing phylogeny is the minutely detailed comparison between (inevitably) a small number of ancient fossils and an equally small number of putatively related extant forms. The enormous time gap is ignored in practice and minimized in theory by the assertion that nothing of great evolutionary importance has happened in the past 350 million years. The Anglo-American methodology on the other hand, also often gravely flawed, has been to search for ancestor-descendant sequences, studying, inevitably more superficially, large numbers of fossil species ranged over the whole span of vertebrate history. Perhaps in the future there will be a meeting of minds, also incorporating the less controversial features of cladistic analysis; but Jarvik's book, admirably scholarly in many ways but perverse in many others, will not promote it.

Alec Panchen, editor of the recent symposium volume The Terrestrial Environment and the Origin of Land Vertebrates (Academic, 1980), is Reader in Vertebrate Zoology at the University of Newcastle upon Tyne.

Nervous molluscs

Steven A. Siegelbaum

Molluscan Nerve Cells: From Biophysics to Behavior. Edited by John Koester and John H. Byrne. Pp.230. ISBN 0-87969-135-2. (Cold Spring Harbor Laboratory: 1981.) \$26, \$31.20 outside the USA.

ONE of the major goals of neurobiologists is to understand how higher processes such as learning and behaviour are related to and controlled by the electrical activity of nerve cells. Until recently, the prevailing view was that what counted most was the pattern of nerve cell connections, the nervous system's wiring diagram, and not primarily the membrane properties of individual nerve cells. However, within the

IRCS Medical Science St. Leonard's House St. Leonardgate, Lancaster, U.K.

A member of Elsevier Science Publishers

past few years, a number of researchers have found that, at least for invertebrates, certain aspects of behaviour and "learning" can be explained surprisingly well at the level of the nerve cell membrane's jonic channels.

These recent findings depend, in large part, on our increasingly detailed understanding of the ionic basis of the electrical activity of nerve cells. In 1952, Hodgkin and Huxley demonstrated that the action potential of the squid axon could be understood in terms of two types of ion channels, one permeable to sodium, the other to potassium. While the Hodgkin-Huxley analysis still provides the framework for our present understanding of the electrical activity of nerve cells, it is now clear that no less than five distinct classes of channels exist. These channels play an important role in a variety of physiological processes, ranging from the control of transmitter release from nerve terminals to regulation of the rhythmic patterns of action potential firing produced by nerve cell bodies.

In view of this rather complex description of the nerve cell membrane, this book provides a welcome survey of recent developments in the field. The first in a new series entitled Cold Spring Harbor Reports in the Neurosciences, the book is composed of transcripts of talks from a recent symposium which concentrated on studies of molluscan nerve cells. The subjects are arranged in a logical order, starting with a discussion of the biophysical properties of ion channels and progressing to how such channel properties control spike generation patterns and behaviour. The book also includes chapters on the regulation of intracellular ions and the membrane effects of neurotransmitters and hormones.

The material has been presented clearly and at a level which should be accessible to readers with no direct experience in the field, while at the same time informative to those more familiar with the subject. The book contains two introductory chapters (by Eric Kandel and Charles F. Stevens) and should be especially useful for graduate students. One, perhaps inevitable, shortcoming of a book with such a wide scope is that some topics are treated rather briefly and uncritically. This is particularly noticeable in areas where some controversy remains, such as the control of channel opening and closing by internal calcium ions and the mechanism of neurotransmitter modulation of the action potential. Still, the book is an excellent summary and introduction to recent findings in the study of molluscan nerve cells and provides an interesting example of how membrane biophysical techniques may be successfully applied to a wide range of biological questions.

A question of the evolution of culture

Robert Attenborough

Man, The Promising Primate: The Conditions of Human Evolution. By Peter J. Wilson. Pp.185. ISBN 0-300-02514-9. (Yale University Press: 1980.) \$12.95, £9.10.

A NINETEENTH-century anthropologist would perhaps have found it unsurprising to read that an author's aim was to "consider human evolution from the point of view of social anthropology". That this aim, which Professor Peter Wilson declares at the outset of his book, does sound a little odd today is a measure of the gulf which has developed over the years between social and biological anthropology, making it conventional now for social anthropologists to leave problems of the evolutionary past to their biological colleagues.

Wilson, no doubt rightly in principle, will not allow such conventions to deter him from pursuing his interest in early human societies, and in doing so he meets head-on the main practical obstacle to his ambition: as he puts it, "social factors leave behind no evidence that can serve as a concrete subject of study". So readers are warned: what follows is, as the author frankly says, a purely speculative argument, and anyone who expects much in the way of facts will be disappointed.

Taken on its own terms, then, what is the nature of this argument? Wilson recognizes the value of the Darwinian perspective; he is willing to imagine that human societies must once have been more like those of apes and monkeys than they now are; and he acknowledges that the human capacity for culture must ultimately be an evolved, genetically based characteristic. But how, he asks, can we explain the emergence of this characteristic in a particular primate genus at a particular period and place? It is a good question, and, although he is by no means the first person to ask it, there is still room for fresh ideas.

The basis of Wilson's ideas is the biological proposition that primates are the most primitive and generalized of mammals, and that human beings are in turn the most primitive and generalized of primates. Lacking the evolved specializations which equip so many other animals for their particular ways of life, human beings must be flexible, they must be ready to make the best of whatever conditions they encounter, and they must do so by choosing from a range of options, rather than by giving standard responses: they must, in fact, be capable of dealing with varied day-to-day conditions of material and social life in ways that are too complicated to be genetically programmed in any specific way. From this need, which is both a constraint and a source of freedom, arose the exceptional characteristically human specialization, the large brain: and with that came the capacities for thought, consciousness and ultimately culture. Human beings are thus "promising primates", creatures of endless potential.

In all this, the focus of Wilson's attention is, naturally, on the social implications. From the generalization of sexual behaviour, he suggests, arises a longerterm mutual interest between males and females, which must be controlled by rules and bonds if it is not to lead to social chaos. The conjunction of the male-female bond with the female-infant bond forms the basis of a third bond between males and infants, and thus the cultural beginnings of kinship, the incest taboo and marriage. But it also creates a social problem, especially for the female, who plainly cannot maintain two close bonds at once. She must divide her attention and her time, and be able to convey the assurance that a neglected relationship will be returned to. Thus human beings must be "promising primates" in a second sense, committing themselves to the future of social relationships.

What, then, should one make of an argument like this? At times, Wilson's advocacy is admirable: serious but also stimulating, ingeniously argued, willing to recognize both primate capabilities and human peculiarities, and (not least of its virtues) well written and not too long. Certainly it deserves the attention of anyone interested in the field. But ultimately it is not altogether satisfying, mainly because its virtues are not maintained consistently. Sometimes Wilson labours too hard over a step in the argument, and the style suffers. And frequently he raises points of detail which tempt the reader to stop and quibble. Moreover, not all points of disagreement are mere details: let me give two illustrations.

The first concerns the use of the concept of generalization. There is, of course, more than a little truth in the notion of human beings as a biologically generalized species (though not in the idea that generalized is synonymous with primitive). But Wilson presses the concept of generalization much further than a biologist would be happy to, relying on it almost as though it were a physical law, a force which, once invoked, carries all aspects of anatomy and behaviour irresistibly along in a single current of evolutionary change. This takes Wilson away from his own correct insis-

Principles of Optics

Pergamon Press have recently published a new edition of *Principles of Optics* by Max Born and Emil Wolf. The latest edition, the sixth, incorporates revisions to the text and illustrations as well as references to the recent literature. Prices are: hbk £22, flexi £12.

tence on understanding the underlying conditions of human evolution. It also creates difficulties for his argument: most notably, it leads him to treat sexual generalization (i.e. continuous female receptivity) as a given feature of the human species, to which other features must adapt, rather than as a phenomenon to be explained in itself.

The second problematic issue is related to the first. Wilson is fairer-minded than many in the capacities that he is willing to attribute to the non-human primates: but, perhaps because his argument emphasizes their relative specialization, he does not go far enough. To take again the example of sex and bonding, he not only doubts the existence of primate sex drives, he also implies that primates do not have multiple social relationships to sustain, as early

human beings, he postulates, did. There is surely no shortage of evidence to refute this suggestion: and if one concedes this point, then Wilson's explanation of why human capacities emerged when and where they did must lose much of its force.

With flaws such as this, Wilson's argument is far from being fully persuasive, even at the frankly speculative level which he intends. But he has taken more trouble than many to present a balanced view of early human societies and, despite its less than total success, his book deserves to be read by anyone with an interest in its theme.

Robert Attenborough is a Lecturer in Biological Anthropology in the Department of Prehistory and Anthropology, Australian National University, Canberra.

Electrochemistry, principles to practice

A.J. Nozik and R.J. Gale

Electrochemical Methods: Fundamentals and Applications. By A.J. Bard and L.R. Faulkner. Pp.718. ISBN hbk 0-471-05542-5; ISBN pbk 0-471-08753-X. (Wiley: 1981.) Hbk £21, \$39.85; pbk £11.75, \$21.70.

THE field of electrochemistry is currently undergoing a major renaissance, now having a central role in such exciting research areas as photoelectrochemistry, chemically modified electrodes, novel energy conversion systems and medical electronics. These fast-moving disciplines all involve a high degree of interaction between solid state physics, physical chemistry, photochemistry, surface science, engineering and electrochemistry. The appearance of *Electrochemical Methods*, which provides a clear and thorough account of all aspects of its subject, is thus timely.

The book is encyclopaedic in scope, covering both basic principles of electrochemistry and all the modern and relevant electrochemical and electroanalytical techniques; it is truly an exceptional resource for both practising electrochemists and those eager to learn about this frequently intimidating subject. In addition to the expected material on electrochemical principles and techniques, the book also has a nice, concise introductory chapter on spectroelectrochemistry and photoelectrochemistry; this includes material on optical, electron and ion spectrometry and related phenomena.

The audience for the book will be large since it will also serve as a textbook for senior undergraduate and beginning graduate students. It is the first comprehensive text to cover electroanalytical theory and techniques since Lingane's (Electroanalytical Chemistry; Interscience, 1958) and Delahay's (New Instrumental Methods in Electrochemistry; Interscience, 1954)

books of the 1950s. Since then, the subject has grown enormously and the range of modern techniques has necessitated a reevaluation of the emphasis in applications. This has been successfully achieved in this text, and it should prove to be of considerable value in advanced courses in electroanalytical chemistry.

The omission of laboratory procedures is not especially troublesome since this area is complemented by Adams' Electrochemistry at Solid Electrodes (Dekker, 1969) and Sawyer and Roberts' Experimental Electrochemistry for Chemistry (Wiley, 1974). The absence of the more 'classical'' electrochemical topics could be a problem as most electroanalytical courses require at least a review of this material. It might also have been more appropriate to introduce concepts of the double-layer at an earlier stage than Chapter 12; Chapter 9 should be singled out as an excellent introduction to impedance concepts. The emphasis and presentation of the subject material are superlative throughout and the text could not be improved without considerable expansion in size and cost. An additional bonus is the problems, which provide useful exercises in the more important concepts and topics.

Very few errors have been noted; however, Problem 9.4 (p.368) does not tabulate the frequency as indicated, and the axes in Figure 14.8.2 (p.655) are labelled in an ambiguous (unconventional) manner.

This text has filled a definite need in present-day electroanalytical literature. We recommend it highly to students, teachers and research scientists.

A.J. Nozik is Chief of the Photoconversion Research Branch at the Solar Energy Research Institute, Golden, Colorado, and R.J. Gale is an Assistant Professor in the Department of Chemistry at Louisiana State University, Baton Rouge.

Ionic solutions

A.K. Covington

Ionic Liquids. Edited by D. Inman and D.G. Lovering. Pp.450. ISBN 0-306-40412-5. (Plenum: 1981.) \$49.50, £31.19.

Most conference volumes are conceived before the meeting itself takes place, and these days contributors are expected to arrive with camera-ready copy or place their expenses in jeopardy. The decision to publish the papers from this conference organized jointly by the Electrochemistry and Molten Salts Discussion Groups of the Chemical Society (now the Royal Society of Chemistry) apparently arose during the conference at St John's College, Oxford, in July 1978. The intention of the meeting organizers was to provide a greater exchange of ideas between aqueous solution chemists and molten salt chemists, thereby focusing attention on the somewhat neglected area of the properties of concentrated electrolyte solutions.

As with most conference volumes, the quality, approach and style of the 20 presentations are variable. Particularly valuable, however, are Enderby's account of the important neutron scattering first order difference method of determining radial distribution functions, and hence cation and anion hydration in concentrated solutions such as NiCl₂/D₂O, CaCl₂/D₂O, Duffy and Ingram's account of acid-base properties of concentrated aqueous solutions, and Adams and Hills's perceptive survey of computer simulation methods. The latter authors are somewhat scathing in their criticism of the preoccupation of solution chemists with continuum theories. In this connection, one of the contributors (Richter) quotes a 1957 paper of Fuoss and Onsager who thought that the problem of concentrated salt solutions should be approached from the fused salt side. Little progress has been made in those 24 years although recent approaches by Blander (Argonne), who was not a contributor, look promising.

Several papers highlight problems of technological interest — Dead Sea brines (Marcus), aluminium halide containing melts (Osteryoung) and sulphur and sulphide species in melts (Plichon) — and restore the balance towards practical aspects. Four papers deal with various aspects of water in melts: industrial and electrochemical (Lovering), concentration dependence of transport properties (Claes), solution chemistry (Coombes), and effect on purification (White).

The book is excellently produced with good, clear diagrams. It is to be recommended with the hope that it will, by placing the problems in perspective, encourage that progress which was the aim of the organizers.

A.K. Covington is Reader in Physical Chemistry at the University of Newcastle upon Tyne.

ATTOUT CEMENTS

Awards

Dr Paul Rebut (deputy director of JET) has been awarded le Grand Prix de Physique Jean Ricard for 1981 by the Council of the Societé Français de Physique (SFP).

The annual Karl Heinrich Gyr and Heinrich Landis Commemorative Prize, which is administered by the Institution of Electrical Engineers, has been awarded to Mr Martin Weston of the BBC.

The International Union Against Cancer, with the funds provided by the American Cancer Society, will award Eleanor Roosevelt Fellowships for research on cancer only to persons on the staff of universities, teaching hospitals, research laboratories or similar institutions, and to investigators who are devoting themselves to the experimental or the clinical aspects of cancer research. The Yamagiwa-Yoshida Memorial International Cancer Study Grants are funded by the Japan National Committee for the UICC. These Study Grants are also administered by the International Union Against Cancer. They are designed to enable investigators of any nationality to gain experience in, or make comparative studies of, special techniques in both the biological and clinical aspects of cancer research. Application forms and information additional from: International Union Against Cancer, rue du Conseil-Général, 3, 1205 Geneva, Switzerland.

Twenty Harkness Fellowships tenable for between 12 and 21 months are offered each year. The award includes return fares to the United States, living and family allowances, travel in America (with car rental allowance), tuition and research expenses, a book and equipment allowance and health insurance. Candidacy is open to men and women between 21 and 30 years of any profession or field of study, who are citizens of the UK and have recieved both secondary schooling and further education (or equivalent professional experience in lieu of further education) wholly or mainly in the United Kingdom. For application forms: send a s.a.e. carrying 26p postage, and measuring not less than 10 inches by 7 inches, to The Harkness Fellowships (UK), Harkness House, 38 Upper Brook Street, London W1, UK.

Meetings

13-16 October, Indoor Air Pollution, Health and Energy Conservation, Massachusetts (Dr J.D. Spengler, Dept of Environmental Health Sciences, Harvard School of Public Health, 665 Huntington Ave, Boston, Massachusetts 02115, USA). 14 October, Geological Aspects of the Disposal of Radioactive Waste in the Sea, London (Mineralogical Society, 41 Queen's Gate, London SW7, UK).

18-23 October, Water Chlorination: Environmental Impact and Health Effects, California (Dr R.L. Jolley, Oak Ridge National Laboratory, PO Box X, Oak Ridge, Tennessee 37830, USA).

19-22 October, Pattern Recognition, Munich (Prof. Dr H. Marko, Lehrstuhl für Nachrichtentechnik der Technischen Universität München, 8000 München, FRG).

19-21 October, Spectroscopic Methods for Biomedical Research, Columbus (K.L. Waite, Batelle's Columbus Laboratories, 505 King Avenue, Columbus, Ohio 43201, USA).

23-24 October, The Role of Receptors in the Skin, Nice (Prof. Hans Schaeffer, CIRD, Sophia Antipolis, F-06565 Valbonne, France).

27-30 October, 10th European Symposium on Clinical Pharmacological Evaluation in Drug Control: Drugs for Infants and Children, Schlangenbad (World Health Organization, 8, Scherfigsvej, DK-2100 Copenhagen Ø, Denmark).

25-28 October, Laboratory Health and Safety, Loughborough (Centre for Extension Studies, University of Technology, Loughborough, Leicester, UK).

25 October — 7 November, Plant Tissue Culture Methods and Applications in Agriculture, Los Banos (Dr T.A. Thorpe, Dept of Biology, University of Calgary, Calgary, Alberta, Canada T2N 1N4).

27-29 October, Polynuclear Aromatic Heterocarbons, Columbus (D. Cooley, Battelle's Columbus Laboratories, 505 King Ave, Columbus, Ohio 43201, USA). 29-31 October, Rural Development and Retention of the Rural Population in the Countryside of the Developing Countries, Ottawa (J. Havet, Institute for International Cooperation, University of Ottawa, 190 Laurier Ave East, Ottawa, Ontario, Canada K1N 6N5).

29-30 October, Office Health and Safety, Loughborough (Centre for Extension Studies, University of Technology, Loughborough, Leicester, UK).

31 October — 2 November, Annual Meeting of the American Society for Cybernetics, Washington (Dr L.D. Richards, Dept of Administrative Science, Colby College, Waterville, Maine 04901, USA).

3-6 November, Working Group on Appropriate Technology for Health in Radiology, Radiotherapy and Nuclear Medicine, Rome (World Health Organization, 9, Scherfigsvej, DK-2100 Copenhagen Ø, Denmark).

3-6 November, Health and Safety at Work, Wembley (Maclaren Exhibitions Ltd, Davis House, 69-77 High St, Croydon, UK).

3-9 November, Remote Sensing of Arid and Semi-arid Lands, Cairo (E.S. Kasischke, Environmental Research Institute of Michigan, PO Box 8618, Ann Arbor, Michigan 48107, USA).

4-6 November, **EFOC** '81, Cologne (Information Gatekeepers Inc. c/o Tom Wearden Associates Ltd. 11 Chalmore Gardens, Wallingford, Oxon, UK).

9-11 November, Mechanical Behavior of Salt, Pennsylvania (Dr H. Reginald Hardy Jr, Rock Mechanics Laboratory, Room 117 Mineral Sciences Building, The Pennsylvania State University, University Park, Pennsylvania 16802, USA).

7-8 November, 32nd Annual Meeting of the American Association for the Study of Liver Diseases, Chicago (Charles B. Slack, Inc. 6900 Grove Rd, Thorofare, New Jersey 08086, USA).

9-13 November, 1981 Postgraduate Course in Clinical Pharmacology, Drug Development and Regulation, New York (Dr W.M. Wardell, Dept of Pharmacology, The University of Rochester Medical Center 601 Elmwood Ave, Rochester, New York 14642, USA). 11 November, Precambrian—Cambrian Evolutionary Explosion, Bristol (Dr R.

Evolutionary Explosion, Bristol (Dr R. Riding, Dept of Geology, University College, Cardiff, UK).

19-21 October, Working Group on Legionnaires Disease, Baden (World Health Organization, 8, Scherfigsvej, DK-2100 Copenhagen O, Denmark).

12-13 November, Advisory Committee on Prophylactic, Diagnostic and Therapeutic Substances, EURO (World Health Organization, 8, Scherfigsvej, DK-2100 Copenhagen O, Denmark).

14-19 November, Seminar on Appropriate Technology for Drinking Water Demineralization, Algiers (World Health Organization, 8, Scherfigsvej, DK-2100 Copenhagen O, Denmark).

12-13 November, Common Denominators in Art and Science, Edinburgh (Prof. M.R. Pollock, Marsh Farm House, Margaret Marsh, Shaftesbury, Dorset, UK).

16-17 November, HPLC of Proteins and Peptides, Washington (R. Schulthess, Varian AG, Steinhauserstrasse, 6300 Zug/Switzerland).

17-19 November, Taking Industry Offshore, London (IMechE, 1 Birdcage Walk, Westminster, London SW1, UK).

18-19 November, Business Opportunities in Genetics, Madison (C.W. Little, University of Wisconsin Extension, Dept of Engineering, 432 North Lake St, Madison, Wisconsin 53706, USA).

16-17 December, Structure of the Interfacial Region, Oxford (Dr M. Lal, Unilever Research, Port Sunlight Laboratory, Bebington, Wirral, Merseyside, UK).

17-20 December, Annual Conference of The Palaeontological Association, Exeter (Prof. J.W. Murray, Dept of Geology, University, Exeter, UK).

NEW ON THE MARKE

Colorimeter. Brinkmann Instruments Inc. have produced four new dipping probe colorimeters. These use a fibre optic light guide and detector system, and a specially designed dipping probe which is inserted into the solution to be measured. Phaseshifted, a.c. modulated light is transmitted to the probe tip and back to silicon detectors through an interference filter. This system allows measurements to be made without any effects due to extraneous or ambient light. Models PC-700 (analogue) and PC-800 (digital) have slidein interference filters which cover the visible range of the spectrum. Probe tips are available in stainless steel, glass and polycarbonate (Lexan). The diameter of the probe tip is ≤ 1 cm, thus it can be easily inserted into a test tube and readings made for a sample as small as 0.5 ml. These colorimeters have applications in the chemical and pharmaceutical industries.

Circle No. 90 on Reader Enquiry Card.

Ultrasonic system. Rinco Ultrasonics have just announced their new Bio 70, which is claimed to be the smallest ultrasonic system for biological, chemical and botanical investigations. The silent probe, which is no larger than a fountain pen, operates at 70 kHz and is powered by a portable 50 W generator, which weighs only 6 kg. Now the complete ultrasonic apparatus can be carried to the working area which decreases the possibility of cross-contamination.

Circle No. 91 on Reader Enquiry Card.

Hg vapour detector. The Data Acquisition 1500.DP5 mercury vapour detector can be easily connected to a chart recorder to provide a permanent record (and alarm) of the mercury level over a period of time. The instrument reads from $0.5 \mu g \text{ m}^{-3}$ to $1,999 \mu g \text{ m}^{-3}$ on a digital display and has its own integral charcoal filter for ease of zeroing in hazardous areas. It can be used either as a permanent or portable unit.

Circle No. 92 on Reader Enquiry Card.

Particle size analyser. The latest particle size analyser from CILAS provides extremely fast and accurate measurement of powders. It measures the diffraction of a coherent light beam by grains of the powder which are held in suspension in a suitable liquid medium. Average measurement time is 5 min and reproducibility is within $\pm 1\%$.

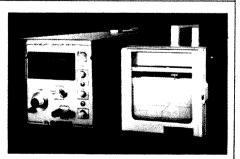

Circle No. 93 on Reader Enquiry Card.

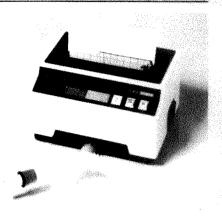

Thin film production. New from Balzers is the BAK 760, a system used for precision resistor networks and hybrid circuits where resistant and contact evaporation coatings need to be applied. As well as applying thin film to integrate circuits or liquid crystal displays, large quantities of ceramic rods coated with Ni-Cr for the production of highly stable metal-coated resistors can be processed in a tumble-cage device. Film thickness and evaporation rate are measured and adjusted during the evaporation process by the quartz crystal method and the results shown on a display. Based on these values, the microprocessor can control up to four evaporation sources and can be programmed in any desired order. The capacity of the BAK 760 ranges from 2-inch diameter to 4×4 inch substrate. The cage evaporation device has a capacity up to 31.

Circle No. 94 on Reader Enquiry Card.

Agar dilution. The agar dilution method of antibiotic susceptibility testing has long been thought to have distinct advantages over the disk diffusion method. However, there have been practical problems in the preparation of plates incorporating antibiotics. Mast Laboratories announce a major new product, ADATAB, which overcomes these problems and allows agar dilution to be used for routine susceptibility testing. Adatab consists of accurately assayed quantities of antibiotic in an inert non-interfering soluble carrier. By placing one Adatab in 100 ml of culture medium and allowing 3 min for the carrier to dissolve, six plates of a specific recommended antibiotic breakpoint concentration can be poured. This can be easily scaled up for the larger laboratory. A range of concentrations for MIC work can be prepared as required.

Circle No. 95 on Reader Enquiry Card.

Spirometer. The VS400 volume displacement spirometer can be used to perform an inexpensive and simple test for the screening of lung disorders. The VS400 is a waterless spirometer with a three-colour pen turret for simplified and accurate evaluation. The instrument has a colour-coded instruction panel, and its easy-loading card carrier and automatic or manual start make it simple to operate. The VS400 provides a volume versus time trace. Circle No. 96 on Reader Enquiry Card.

Log amplifier module. New from Bryans Southern Instruments Ltd. is a log amplifier module, an addition to the range of modules available for their high quality 50000 x-y recorder range. The new log amplifier module is designed for both A4 and A3 modular mainframes and can be easily fitted by the user. This d.c. module can be used in either the x or the y axis and if two log amplifier modules are used together, log-log plots can be recorded on a 50000 unit. Other modules for the Bryans 50000 range of high performance recorders include: low and medium sensitivity amplifiers with variable gain controls, single sensitivity amplifiers and time base/control modules.

Circle No. 97 on Reader Enquiry Card.

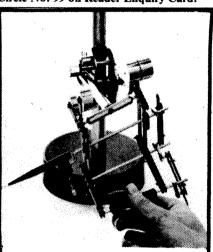

Sterilizable O₂ electrode. New Brunswick Scientific Ltd. has developed a dissolved oxygen electrode with replaceable membrane that can be rejuvenated repeatedly. The Model 900 probe rapidly responds to changes in oxygen partial pressure in biological and chemical processes. A 90% response time is reached in 60 s and linearity and reproducibility are 1% at constant temperatures. Mounted in a type 316 stainless-steel housing, the Model 900 is available in eight lengths for vessels ranging in size from 1 to > 1,000 l.

Circle No. 98 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the journal.

Coliform and streptococcal detection. Fast, accurate measurement of bacterial contamination in food, drink and pharmaceutical production is now possible using two kits from LUMAC. The streptococci detection kit allows selective measurement of streptococci after a short incubation, and the coliform detection kit selectively measures coliforms and therefore tests the hygiene of production processes. Both methods are simple, convenient and are up to 5 days quicker than conventional plate-counting techniques.

Circle No. 99 on Reader Enquiry Card.

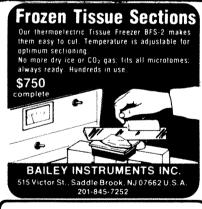

SINGER MICROMANIPULATORS ARE FAMOUS BECAUSE

Singer Micromanipulators enable anyone to make exact movements without tremor or lost motion, in three dimensions, using a single control handle under low or high power magnification.

A varied range available. All simple to operate.

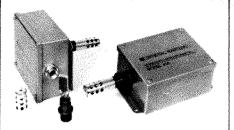

SINGER INSTRUMENT CO. LTD., Treborough Lodge, Roadwater, Somerset.

High Resolution RADIOISOTOPE CAMERA (Spark Chamber)

The new HIGH RESOLUTION Radioisotope Camera produces a polaroid print of the distribution of radioactive compounds, Tritium and Carbon — 14, on Thin Layer Plates and Paper radiochromatograms.

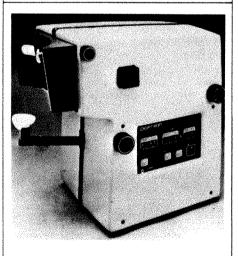

Birchover Instruments Ltd THE SPIRELLA BUILDING BRIDGE ROAD, LETCHWORTH HERTS, SGBEET ENGLAND TELEPHONE: LETCHWORTH (04626) 73097

Relative humidity transmitters. General Eastern announces a new line of per cent relative humidity and temperature transmitters — the 455 Series. These instruments are available in duct or wall-mount versions, for 115 V/230 V a.c. or ± 24 V d.c. inputs. The Model 455 provides linear 0–10 V d.c. and 4–20 mA d.c. signals for 0–100% relative humidity, and 0–12 V d.c. and 4–20 mA d.c. for 0 to +120°F. Accuracies for the measurements are $\pm 3\%$ relative humidity, between 15 and 99% relative humidity, and ± 1 °F over the entire temperature span.

Circle No. 100 on Reader Enquiry Card.

Dri-Blocks. A Techne Dri-Block can be used with Sterilin specimen containers for a more convenient method of fertility testing. A sperm sample is collected in a Sterilin 60 mm Universal clear-labelled container and heated in a special Techne Dri-Block heater for 20 min at 37°C. This ensures that the sperm is at body temperature before a sperm count is taken. The Techne Dri-Block has an advantage over a water bath in that the sperm would die if they accidentally came in contact with the water. Techne Dri-Blocks are available to cover a temperature range of 25 to 450°C. **Circle No. 101 on Reader Enquiry Card.**

Portable autorefractor. A compact, portable autorefractor, Dioptron Nova, has been developed by Coherent. It features the Coherent Auto Fog system which eliminates instrument myopia and is particularly suitable for over-refracting contact lenses. It also allows immediate vertex distance conversion from spectacles to contact lenses at the touch of a button. Circle No. 102 on Reader Enquiry Card.

Vapour adsorption cartridges. A new series of microfibre vapour adsorption cartridges has been introduced by Balston, Inc. These are designed to carry out various tasks such as removing oil vapour from compressed air, purifying breathing air, removing water vapour from a gas stream, and removing mercury vapour from gas. Designated type CI, the new cartridges are available with a choice of six standard adsorbents, including carbon, Ambersorb XE-348, silica gel, molecular sieve type 4A and 13X, and Calgon type HGR sulphurimpregnated carbon. They contain a bed of adsorbent granules in the annular space between two microfibre filter tubes, with permanently bonded end caps, and fit all standard Balston compressed gas filter housings and many cartridge filter housings of other manufacturers.

Circle No. 103 on Reader Enquiry Card.

NEW LITERATURE

Dewars. The extended range of dewars from Day-Impex Ltd. is covered in their new leaflet. Circle 150.

Affinity-isolated antibodies. Antibodies to all human immunoglobulins and mouse IgG and IgM are featured in a new catalogue from Tago, Inc. Circle 149.

Liquid handling devices. Various μ l liquid handling devices are described in a new catalogue from Drummond Scientific. Calibrated micropipettes and variable volume positive displacement digital micropipettors are included. Circle 148.

Aluminum film guide. The 'Aluminum Film Guide' from the Aluminum Association lists 30 films about aluminum from various sources. Circle 147.

Products. The range of products available for tissue culture, microbiology, serology, clinical chemistry and immunology is given in a new catalogue from Gibco. Circle 146.

Steric exclusion analysis. An applications note describing steric exclusion analysis of coatings and adhesive polymer formulations by HPLC is available from Varian. Circle 145.

Capillary columns. A new brochure from Analabs contains information on glass and metal capillary columns and column accessories for gas chromatography. Circle 144.

Freeze drying. 'Laboratory Freeze Drying Systems and Accessories' from Techmation introduces the theory and practice of freeze drying and gives full details of VirTis freeze drying equipment. Circle 143.

Air analysis. Types of industrial hygiene air analysis sampling by atomic absorption are described in a new applications note from Varian. Circle 142.

Copies of these publications can be obtained using the reader enquiry card.

UNIVERSITY OF ST. ANDREW'S **DEPARTMENT OF ASTRONOMY** Applications are invited for a POSTDOCTORAL RESEARCH ASSISTANT

to work on an SERC supported project investigating the properties of marginal contact and non-contact binary stars. The project involves optical and near-infrared photometry and high-dispersion spectroscopy using facilities at major international observatories. Applicants should have some experience in optical observational techniques and an interest in computational work.

The appointment will be for a period of three years from 1st October 1981 or as soon as possible thereafter. Initial salary in the range of £6,070 to £6,880 per annum on range 1A plus superannuation.

Applications together with the names of two referees should be sent by 24th August, 1981 to The Director, University Observatory, Buchanan Gardens, St Andrews, Fife KY16 9LZ, Scotland, from whom further particulars may be obtained. (9274)A

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

APPLIED PIG NUTRITION DEPARTMENT

A vacancy exists for a scientist to participate in a programme of research now being developed on nutrition and lactational physiology in the sow. The work will include studies of the energy nutrition of the sow during gestation and lactation, and on the hormonal control of mammary gland function and will involve close collaboration with the Nutrition and Physiology departments.

Candidates should have a First or Upper Second Class Honours degree in Biochemistry or Physiology.

Appointment will be as Scientific Officer (£4,809 to £6,480) or Higher Scientific Officer (£6,075 to £7,999); at least two years' relevant research experience is required for appointment to the higher grade.

Application forms are obtainable from the Secretary, NIRD, Shinfield, Reading RG2 9AT.

Quote reference 81/20 (9275)A

ROTHAMSTED EXPERIMENTAL STATION Harpenden, Herts AL5 2JQ Temporary Appointment **PHYSICIST**

THEORETICAL PHYSICIST

to work in the Physics Department for a period of $2\frac{1}{2}$ years on the development of physical/numerical models of the effects of drought on growth and yield of cereal crops. The modelling will be based on plant and crop physiological principles, and the work (which may include some field work) will involve collaboration with physicists, physiologists, chemists and agronomists. The post is funded by EEC and may be extended by a further few months.

Qualifications: First or upper second class honours in physics, or applied or theoretical physics, and preferably a higher degree, or equivalent post-graduate experience, in research that has included much computer analysis of experimental results and development of physical/ mathematical models.

Appointment in grade of Scientific Officer (£4,809 - £6,480) or Higher Scientific Officer (£6,075 - £7,999). (Pay Award pending). At least two years' post-qualifying experience is required for appointment as HSO. Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of three referees and quoting Ref. 451 by 31st August 1981. Further details on (9252)A request

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London) DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

Physicist or physical chemist required to join research group working on dynamics of bio-membranes. Experience of optical methods and laser techniques would be an advantage. Post is tenable for 3 years, supported by the SERC.

Salary on Range 1A: £7,037 to £11,542 (inclusive). Applications (cv and names and addresses of two referees) should be sent to the School Secretary, RFHSM, 8 Hunter Street, London WC1N 1BP as soon as possible. Please quote ref: SERC/B. (9284)A

INTERNATIONAL LABORATORY FOR RESEARCH ON ANIMAL DISEASES

Scientific Research **Position**

International Laboratory for Research on **Animal Diseases** (ILRAD)

A vacancy exists in the Pathology Division of ILRAD for a Research Scientist to continue studies on the inductive mechanisms for cellmediated immunity against the protozoan parasite Theileria parva in cattle and to analyse the antigenic composition of the parasite. Opportunities exist for collaborative research on surface markers of bovine lymphocytes and means of eliciting protective immunity against Theileriosis.

The applicant should possess a degree in Veterinary Science (or be familiar with experimentation in livestock) together with a PhD. Relevant postdoctoral experience would also be an advantage. Salary will be paid in US dollars according to experience. Perquisites include movement, housing and commutation allowances, medical and retirement benefits.

Applications with curriculum vitae and the names of three referees should be addressed to: The Director of Administration, ILRAD, PO Box 30709, Nairobi.

Closing Date: August 31st, 1981.

(W396)A

CHAIRMAN DEPARTMENT OF GENETICS

The University of Utah, School of Medicine, Salt Lake City, Utah, invites nominations and applications for the position of Professor and Chairman of the new Department of Genetics. This position requires a person with an outstanding research program in genetics, as well as, administrative and leadership qualities, who will interact with both clinical and basic science faculty. This new department will provide the opportunity and requirement to recruit strong faculty.

The university is an equal opportunity/affirmative action employer, thus applications from women and minorities are encouraged.

Inquiries including a curriculum vitae, should be sent to Dr John A Dixon, Chairman Genetics Search Committee, Department of Surgery, School of Medicine, Salt Lake City, Utah 84132. Closing date September 15, 1981. (NWX764)A

scientists

Monsanto, a large organization with European Headquarters in Brussels and Research facilities in pleasant surroundings at Louvain La Neuve, 30 km South of Brussels, is expanding its Agriculture Research Programs in the field of plant growth regulators.

The Biological Evaluation section intends to make new appointments for **scientists** with the ability to carry out and direct fundamental and applied research projects. These projects will be related to the discovery and development of plant growth regulators for use in major arable crops.

Applicants should have a PhD in plant science or agronomy a strong background of plant/crop physiology, preferably 2 years of experience in applied crop research and a proven ability to supervise research teamwork.

Candidates should apply in writing to Personnel Department Monsanto Technical Center, rue Laid Burniat, B-1348 Louvain La Neuve, Belgium.

Monsanto

Biophysicist/ Bioengineer

Are you the seasoned professional to pilot our new venture?

If so, you'll have full responsibility for the development and sales positioning of a new business activity and you'll be applying your knowledge of ceil culture and fermentation to the design, manufacture and marketing of diagnostic instrumentation and allied materials/equipment.

You'll need several years of solid experience in an industrial/educational environment ... with emphasis on the formulation and packaging of biological/medical commercial applications . . . as well as an advanced degree in biophysics or bioengineering or its equivalent.

The new technology is fully developed . . . all ready for your implementation. Our compensation and benefits are liberal . . . and your future will grow along with the project's success

Please send resume and salary history to:

BOX No NW804 Nature, c/o Macmillan Journals Ltd. 4 Little Essex Street, London WC2R 3LF

TECHNICAL AND
NATURAL SCIENCES
(TechnischNaturwissenschaftliche
Fakultät)
of the
Johannes Kepler University
Linz, Austria
the position of a full

PROFESSOR IN BIOPHYSICS is vacant

The candidate for this post will be expected to devote his research activites to experimental membrane biophysics as his main effort. His teaching should be focussed on courses, which enable graduate students in physics, chemistry, computer sciences and mathematics to acquire knowledge in biophysics. Applicants should be proficient in German.

Applications including a curriculum and a list of publications should be sent before October 30th, 1981, to the dean (Dekan) of the Faculty, Altenbergerstr. 69, A-4040 Linz, Austria. Dean Prof Dr Bruno Buchberger. (W397)A

LINCOLN COLLEGE Canterbury, New Zealand

LECTURER/SENIOR LECTURER IN ANIMAL SCIENCE

(Growth and Development)

The Council of Lincoln College, University College of Agriculture, Canterbury, New Zealand, invites applications for appointment to the position of Lecturer/Senior Lecturer in Animal Science (Growth and Development) in the Animal Science Department within the Animal Sciences Group.

Applicants should hold a degree in Agricultural Science or its equivalent and postgraduate experience in the field of growth and development in animals. The appointee will be expected to contribute to the teaching programme of animal science to students at degree and postgraduate levels, and to contribute to the research programmes of the department in the fields of animal nutrition and disease and sheep breeding.

The successful candidate will be appointed as Lecturer or Senior Lecturer at a salary commensurate with his/her qualifications and experience. Current academic salary scales are: Lecturer NZ\$19,140—\$23,520; Senior Lecturer NZ\$24,110—\$27,589 Bar—NZ\$30,035.

Travel and removal expenses will be reimbursed to specific limits. New Zealand Government Superannuation will be available.

Conditions of Appointment giving further details of this position may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the College.

Applications close on 16 October 1981. (9269)A

MASSEY UNIVERSITY Palmerston North, New Zealand

LECTURER IN BOTANY

A vacancy exists in the Department of Botany and Zoology for a lecturer in Experimental Botany. Consideration will be given to all suitably qualified applicants, but preference will be given to those with research experience and/or special interests in:- (i) plant cell biology; (ii) physiological plant ecology; and/or (iii) plant biosystematics.

The appointee will be expected to teach internal and extra-mural students at the undergraduate level, contribute to postgraduate teaching, and establish and develop research in his/her own field of interest.

Salary on the Lecturers scale:-NZ\$19,140 — \$23,520.

Further details of this position and of the University, together with the general conditions of appointment may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF or the Registrar of the University.

Applications close on 1. September 1981. (9270)A

Molecular Biology — Virology — Immunology Syngene Products and Research — Colorado

Applications are invited from research scientists (Ph.D. or M.D.) and technicians (B.S. or M.S.) to join Syngene Products and Research, Inc. (SPAR), a TechAmerica Group Company. TechAmerica Group, Inc. is a rapidly growing company with advanced production and marketing capabilities. We are forming a diverse group of energetic, creative scientists for the purpose of developing new products for use in animal and human medicine and agriculture.

Recombinant DNA - gene splicing and expression

Virology Hybridomas - development of new vaccines - monoclonal antibodies for affinity

chromatography, diagnostics and serotherapy

Biochemistry

- isolation and sequencing of proteins

Microbiology

- physiology and fermentation technology We encourage publication and sponsor cooperative research

programs with university groups, and private research companies. SPAR laboratories are near Colorado State University in Fort Collins. located about 110 Km north of Denver, Colorado. Climate and recrea-

tional opportunities are excellent Attractive salaries and benefits, and generous bonus programs are

offered

THE UNIVERSITY OF AUCKLAND New Zealand

ROTANY -LECTURERSHIPS/ SENIOR LECTURESHIP

Applicants should hold, or be nearing completion of, a PhD. Preference may be given to those who have experience in plant pathology, plant breeding, plant genetics, horticulture, or some combination of interests within these fields.

LEIGH MARINE LABORATORY -RESEARCH FELLOWSHIP

Applicants should have a PhD and research experience in some branch of Marine Science. Preference may be given to those whose research work involves diving. The Fellow will have the status and salary of a Lecturer and the appointment will be for 3 years initially.

Present salary scales are — Senior Lecturers NZ\$24,110 — \$27,589 per annum; Lecturers NZ\$19,140 -\$23,520 per annum.

Conditions of Appointment and Method of Application are available from the Assistant Registrar (Academic Appointments), University of Auckland, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications should be forwarded as soon as possible but not later than 12 October 1981.

EDINBURGH AND SOUTH-EAST OF SCOTLAND **Blood Transfusion Service** ROYAL INFIRMARY EDINBURGH EH3 9HB

A vacancy exists for a RESEARCH FELLOW in the Hepatitis Laboratory of the Microbiology Division. The post is for two years in the first instance and could lead to a higher degree.

The successful candidate, who should have a good honours degree (or equivalent experience) in a microbiology-related subject, will be concerned with research into Non-A, Non-B viral hepatitis. Salary on the scale of £5,346 to £6,353 pa (under review).

Telephone: 031-229 7291, ext 27, for job description. (9280)A

IMMUNOLOGIST/ IMMUNOCHEMIST

Staff research position available for experienced researcher with PhD or MD interested in applying new technologies to the study of human disease.

Experience with monoclonal antibody production and isolation of cellular antigens is desirable. Send CV and references to:

Dr. Robert Colvin, Immunopathology - Cox 5, Mass. General Hospital, Boston, MA 02114. (NW798)A

CSIRO

AUSTRALIA

Research Scientist/ Senior Research Scientist

Division of Fossil Fuels North Ryde, New South Wales

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,400 employees — 2,500 of whom are research and professional scientists — located in Divisions and Sections throughout Australia.

Field: Iron Ore Treatment

General: The Division, situated at North Ryde, Sydney, is currently undertaking a study into the pelletizing and treatment of iron ores to assess the possibility for their further treatment in Australia. Particular emphasis has been placed on the development of an understanding of the mechanism of direct reduction processes of both pellets and lumps. The application of these processes is influenced by the availability and efficient utilization of fossil fuels, especially natural gas and coal, and it will be necessary to include energy aspects of mineral processing in the research.

Duties: To carry out a theoretical and experimental investigation designed to explain the influence of process variables and ore types on the mechanism of pelletizing and reduction, and on the properties of the product.

Qualifications: PhD in metallurgy, chemical engineering, fuel technology or other appropriate fields. Alternatively, equivalent research experience together with a record of achievement relevant to mineral or fuel processing.

Salary: Research Scientist/Senior Research Scientist; \$A19,662—\$A28,564 pa.

Tenure: Indefinite with superannuation.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number A3970 should reach: The Personnel Officer, Australian Scientific Liaison Office, Australia House, Strand, London WC2B 4LA by 5 September 1981. Applications in USA and Canada should be sent to: The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue NW, Washington DC 20036. Current vacancies in CSIRO appear on PRESTEL page 252903. (9283)A

AGRICULTURAL RESEARCH COUNCIL **FOOD RESEARCH INSTITUTE NUTRITION & FOOD QUALITY DIVISION** Sensory Scientist

Higher Scientific Officer/Scientific Officer

The Institute has a vacancy for a Sensory Scientist in a new group within the Nutrition and Food Quality Division. The person appointed will be responsible for studies of the influence of sensory factors on human dietary intake of salt. The study will involve physiological and behavioural techniques and the person concerned will need knowledge of and interest in both aspects. It will involve other groups concerned with food intake measurement and sensory measurements. Collaboration with clinicians will be necessary. An aptitude for working with people is essential; travelling will be involved and a valid driving licence is essential.

Qualifications: A first or upper second class Honours degree in physiology/psychology or related subjects. Some research experienced with human subjects is desirable. At least 2 years postgraduate experience is required for grading at the higher level.

Salary: (under review)

Senior Scientific Officer - on a scale £6,075 - £7,999. Scientific Officer - on a scale £4,809 - £6,480.

Non contributory superannuation scheme.

Further particulars and application form from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA quoting ref. 81/47.

Closing date: 31st August 1981.

(9258)A

HEAD OF THEORY GROUP DARESBURY LABORATORY

The position of Head of the Theory Group at Daresbury Laboratory will shortly become vacant following Dr. Pendry's appointment to a chair at Imperial College and applications are invited to fill this post. The Theory Group, which forms part of the Theory and Computational Science Division, is expected to play a major role in ensuring the effectiveness of the Laboratory's experimental programme.

There are two major research facilities at Daresbury, a dedicated synchrotron radiation source of x-ray and ultra-violet radiation, based on a 2 GeV electron storage ring which has recently started operation and a major nuclear structure facility based on a 30 MeV tandem Van de Graaff which is nearing completion. An AS 7000 and a CRAY 1 provide the basis of an extensive computing facility which supports this programme as well as supporting university research in computational science.

The Theory Group supports the experimental programme on these facilities, has close collaboration with university scientists and maintains very close links with the Computational Science Group in the Theory and Computational Science Division.

The successful applicant will head a team consisting of nuclear, solid state and atomic and molecular theoreticians. The post will be permanent. Alternatively, the Council will consider secondment from or a joint appointment with the candidate's own establishment.

The appointment will be in the grade of Senior Principal Scientific Officer at a salary within the range £13,364 – £16,250. Salaries are currently under review.

Closing date: 30th September 1981

For further information about the work of the Division please write to or telephone Professor P. G. Burke, Warrington (0925) 65000, Ext. 240.

Applications are invited from either sex and should be sent together with curriculum vitae and the names and addresses of two referees quoting reference number DL/767/ to:

The Personnel Officer

DARESBURY LABORATORY

Science & Engineering Research Council Daresbury, Warrington WA4 4AD.

(9248)A

RESEARCH INSTITUTE OF SCRIPPS CLINIC MOLECULAR GENETICS GROUP

Biochemist is required to join the Molecular Genetics Group at the Associate Member level to work on the mechanism of cell-cell interaction in Dictyostelium discoideum. Applicants should have training in both Molecular Biochemistry and Membrane Biochemistry with demonstrated exceptional productivity and creativity in research.

We offer commensurate salary and fringe benefits.

Please send curriculum vitae and statement of research interest and experience to: Nan Price, Research Institute of Scripps Clinic, Molecular Genetics Group, 10466 North Torrey Pines Road, La Jolla, California 92037.

Application deadline: September 20, 1981. (NW797)A

UNIVERSITY OF BRISTOL

DEPARTMENT OF
ANATOMY
Applications are invited from a

GRADUATE

in biomedical sciences for the post of Research Assistant, Department of Anatomy. The successful applicant would join a small research team investigating the role of the nervous system in birth. No previous experience is necessary but a basic knowledge of nervous physiology would be beneficial. The post is supported by the Medical Research Council for three years. Starting salary £5,285 per annum.

Applications, including cv and names of two referees, should be sent to Dr A J S Summerlee, School of Veterinary Science, Park Row, Bristol BS1 5LS by 21st August, 1981. For further information please telephone Bristol (0272) 24161 ext 616, mornings only. (9286)A

UNIVERSITY OF EDINBURGH

DEPARTMENT OF HUMAN
GENETICS

POST DOCTORAL SCIENTIST

Applications are invited for a nonclinical scientist to study DNA polymorphisms in muscular dystrophy as a means of carrier detection and prenatal diagnosis. Candidates should preferably have had experience in DNA analysis, and will work in both the MRC Mammalian Genome Unit and this Department. The appointment is for 3 years from a date to be arranged, and the salary scale is that for University nonclinical academic staff.

Applications by September 14 with the names of two referees to Professor A E H Emery, University Department of Human Genetics, Western General Hospital, Edinburgh EH4 2XU. (9263)A

UNIVERSITY OF ALBERTA

DEPARTMENT OF PHARMACOLOGY

FACULTY AND RESEARCH POSITIONS

The University of Alberta, Department of Pharmacology, is seeking applications for a tenure-track faculty position at the level of assistant professor. Applicants should have a PhD in pharmacology or a related discipline, proven research abilities and be enthusiastic and competent lecturers. Closing date October 1, 1981.

In addition the Alberta Heritage Foundation for Medical Research is offering 5-year scholarships (which may be renewed for a further five years) to those with excellent and well documented research skills. These positions have an academic rank (usually assistant professor) and salary similar to that of a regular faculty position, and are designed to provide support for young and very promising investigators. The Department of Pharmacology is seeking applicants for such awards. In the first instance applications should be made to the Department. It approval is given for the applicant to proceed, the appropriate forms will be submitted to the Heritage Foundation for consideration by their Scientific Advisory Committee. The closing dates for completions are September 1, 1981 and April 1, 1982.

Canadian citizens and permanent residents of Canada will be giver preference for thes positions. With this exception, the University of Alberta is an equal-opportunity employer.

Those interested should apply in writing enclosing a curriculum vitae the names of at least three referees and any other relevant information to Dr David Cook, Department of Pharmacology, University of Alberta, Edmonton, Alberta Canada, T6G 2H7. Telephone (403) 432-3575.

During Canadian mail strike University of Alberta, Box 413 Sweetgrass, MT, 59484, USA. (NW799)A

UNIVERSITY OF LEICESTER

DEPARTMENT OF BIOCHEMISTRY
POST-DOCTORAL
RESEARCH ASSOCIATE

Applications are invited for a SERC-supported, post-doctora research associateship to work wit Dr G Turnock on the regulation or RNA synthesis during the synthesis during the synthesion of the synthesis during the synth

The appointment is available fror 1 October 1981 and is tenable for tw years at a salary within the range fc Research Associates, £6,070 - £7,290 dependent upon age an experience.

Applicants should send curriculum vitae and the names c two referees to Dr G Turnocl Department of Biochemistry University of Leicester, Leiceste LE17RH. (9247)A

TRANSGENE

STRASBOURG - FRANCE

TRANSGENE was launched by leading industrial and financial French groups.

TRANSGENE carries out high level research oriented towards applications of medical and industrial importance.

TRANSGENE is now expanding its laboratory and invites applications from:

MOLECULAR GENETICISTS

EXPERTS IN RECOMBINANT DNA TECHNIQUES AND CHEMICAL SYNTHESIS OF DNA

IMMUNOLOGISTS

from the post doctoral level to group leaders to join its first team of highly qualified scientists.

Expertise in the use of Bacillus subtilis, Yeast and Eucaryotic cells as cloning systems is of special interest.

Salaries will be competitive and commensurate with qualification.

Knowledge of French is not necessary.

STRASBOURG is a pleasant historical town, located in the heart of Europe, very close to GERMANY and SWITZERLAND.

The laboratory is located on the University campus and enjoys close contacts with well known groups in fundamental research.

For confidential consideration, send a CV, a list of publications and indication of salary requirements to:

> TRANSGENE S.A attn J-P LECOCQ B.P. 146 67028 STRASBOURG CEDEX

(W392)A

UNIVERSITY COLLEGE **CARDIFF**

DEPARTMENT OF ANATOMY BURSARY

Applications are invited from UK graduates for a Bursary in the above Department tenable in the first instance for one year but renewable up to a total of three years. While researching within the field of the Anatomical Sciences the incumbent would have the opportunity to work for a higher degree. Index-linked stipend of £2,460 includes a fee for limited teaching duties.

Applications, together with the names and addresses of three referees, should be forwarded to Professor J D Lever, Department of Anatomy, University College, PO Box 78, Cardiff CF1 1XL by 28th August 1981. Ref: 2260. (9245)A

IMPERIAL COLLEGE POSTDOCTORAL RESEARCH ASSISTANT

Plant Mitochondria

Biochemist or Plant Physiologist to study control of the NADH dehydrogenases in isolated plant mitocondria. Salary up to £7,847 pa inlcuding London Allowance. Duration 2 years from October 1st 1981.

Applications and enquiries to: Dr J M Palmer, Dept of Pure and Applied Biology, IC London SW7 2BB.

(9266)A

THE UNIVERSITY OF LEEDS DEPARTMENT OF **BIOCHEMISTRY**

Applications are invited for a post of

RESEARCH FELLOW

in the Department of Biochemistry. available from 1 October 1981 for a fixed period of up to three years, for work on the purification and characterization of androgen receptors from human and rat prostate involving the use of affinity chromatography, affinity labelling and monoclonal antibody techniques.

A good honours degree in Biological Sciences and a PhD in Biochemistry or Endocrinology are required. Experience in receptor work, affinity chromatography, affinity labelling and animal experimentation would be an advantage. Salary on the IA Range for Research and Analogous Staff (£6,070 - £10,575), according to age, qualifications and experience. Informal enquiries may be made to Professor W I P Mainwaring (Tel: Leeds (0532) 31751 ext 7437)

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LSŽ 9JT, quoting reference number 83/38/D. Closing date for applications 31st August 1981. (9241) A AGRICULTURAL RESEARCH COUNCIL

FOOD RESEARCH INSTITUTE

NUTRITION & FOOD QUALITY DIVISION

Scientific Officers

The Food Research Institute has vacancies for four Scientific Officers in the Nutrition & Food Quality Division.

Nutritionist

This post is in a new group concerned with studies of the methodology of measuring food intake in man. The officer will be responsible for setting-up and operating a nutrient information and data base. The post calls for a sound background in nutrition and an interest in the application of computers. The Institute shares computer facilities with the John Innes Institute and there is an active computer group with which this officer will interact. Post No. 81/42.

Assistant Nutritionists

These posts are in the Intake Measurement Group. The officers appointed will be concerned with studies of food intake using a variety of techniques and the preliminary processing of data from these studies. The posts call for an interest and aptitude for working with people and some dietetic experience is desirable. The studies will be primarily conducted in the Norwich area; a valid driving licence is necessary. Post Nos. 81/43 and 81/44.

Assistant Sensory Scientist

The person appointed will be responsible for assisting a Sensory Scientist in studies of the influence of sensory factors on the dietary intake of salt. The work will involve both physiological and behavioural techniques and knowledge of one of these areas and an interest in acquiring an understanding of the other will be essential. A valid driving licence is necessary. Post No. 81/48.

Qualifications

Nutritionist: (81/42) - A first or upper second class Honours degree in Nutrition or Food Science with experience of, and interest in, the application of computer techniques.

Assistant Nutritionists: (81/43 and 81/44) - A second class Honours degree in Nutrition or Dietetics with some dietetic experience.

Assistant Sensory Scientist: (81/48) - A second class Honours degree in physiology or related biological sciences.

Salary: On a scale £4,809 - £6,480 (under review). Noncontributory superannuation scheme.

Further particulars and application form from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA quoting the appropriate reference number.

Closing date: 31st August 1981.

(9257)A

TUFTS UNIVERSITY SCHOOLS OF MEDICINE

DEPARTMENT OF PHYSIOLOGY Tufts University has instituted a search for

CHAIRPERSON

Department of Physiology. The Department of Physiology is expected to be a center of research and scholarly excellence, as well as providing leadership in physiology instruction for the School of Medicine, School of Dentistry, School of Veterinary Medicine, and the Sackler School of Graduate Medical Science.

Individuals interested in being considered for this position should direct their letters to Dr Seymour Reichlin, Chairman, Physiology Search Committee, Box 275, New England Medical Center Hospital, 171 Harrison Avenue, Boston MA 02111. Tufts has an affirmative action program. and encourages applications from women and members of minority groups.

(NW771)A

UNIVERSITY OF KENT AT CANTERBURY RESEARCH FELLOW IN THE BIOLOGICAL LABORATORY

Applications are invited for a postdoctoral research fellowship to investigate the immobilisation of cellulases in soils and synthetic humic polymers. The project will be directed by Dr R G Burns and will initially be of two years duration. Applicants should have a first degree in biochemistry or microbiology and a PhD in some aspect of enzymology. Experience in colloid science and immobilised enzymes would be an advantage though not essential. Salary scale £6,070 - £10,575.

Application forms and particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 8NH to whom completed applications should be returned as early as possible but not later than 24 August 1981. Please quote ref. A23/81/N. (9255)A

International Genetic Sciences, Inc. is organizing an annual conference on Introduction of Genetic Materials into Eucaryotic Cells: Present State and Future Prospects

Among the lecturers:

H. Goodman (U. Calif, S.F.), A. Graesman (Free U. W. Berlin), S. Izhar (Volcani Center, Israel), A. Loyter (Hebrew U. Jerusalem), D. Papahadjopoulos (U. Calif, S.F.), F. Ruddle (Yale U.), W. Rutter (U. Calif, S.F.), R. Rott (Inst. Virology, Gissen, W. Germany), R. Shimke (Stanford U.)

Among the topics to be included:

- 1. Transfer of Nucleic Acid into animal cells.
- 2. Introduction of genes into plant cells.
- 3. Use of Liposomes as a carrier of biological materials.
- Fusion mediated transfer of biological materials into animal cells.

Cost of \$450 includes room and meals. No registration fees, Number of participants limited to sixty. The conference to be held at the Harrison Conference Center, Glen Cove, L.I., N.Y. Arrival Nov. 22, 1981; departure Nov.25, 1981.

Interested scientists, please send as soon as possible information including name, address, phone, present position and areas of interest. Send to:

International Genetic Sciences, Inc. 155-25 Styler Rd, Jamaica, NY, USA 11433 or call (212) 526-0400

(NW802)A

THE EUROPEAN MOLECULAR BIOLOGY LABORATORY seeks an

Applications Programmer

for its nucleotide sequence database group in Heidelberg. The group is engaged in collecting and making available the published nucleic acid sequence data and will later pursue analysis and other research tasks related to the database. The laboratory's NORD-10S and VAX 11/780 computer systems currently provide computer support for the work.

The successful applicant will help to design and develop database management, data collection and analysis software for the database system. An interest in applying computer technology to scientific problems would be advantageous, although prior expertise in molecular biology is not essential.

Applicants should have at least a bachelor's degree and 3 to 5 years' experience in an industrial or research setting. Experience with modern software development methodology and block-structure languages (+ Fortran) and a demonstrated ability to develop transportable user-oriented software are essential, as is fluency in English.

The salary offered will be between DM3,300 and DM3,600 monthly, after tax. Certain allowances are payable in addition, depending on personal circumstances.

Please write briefly for an application form, quoting reference No. 81/12, to: EMBL, Personnel Section, Postfach 10.2209, D - 6900 Heidelberg, Germany.

(W398)A

UNIVERSITY COLLEGE CARDIFF

(Re-advertisement) CAREERS ADVISER CARDIFF JOINT UNIVERSITY CAREERS & APPOINTMENTS SERVICE

Applications are invited for the post of Careers Adviser in the Cardiff Joint University Careers and Appointments Service. Salary Range: Administrative Staff Grade 1A/2£5,285—£12,860 pa. Duties to commence as soon as possible. Successful careers advisers have come from many varied backgrounds. Have you the right qualities, eg relevant degree, related experience, to help students in the biological and life sciences launch their careers?

Applications (2 copies) together with the names and addresses of two referees should be forwarded to the Vice-Principal (Administration) and Registrar, University College, PO Box 78, Cardiff CF1 1XL, from whom further particulars are available. Closing date 26th August 1981. Ref: 2255. (9251)A

UNIVERSITY OF LONDON GOLDSMITHS' COLLEGE

School of Science and Mathematics

TEMPORARY LECTURER IN PHYSICS

Applications are invited for the two year appointment as a Temporary Lecturer in Physics available from the 1st January 1982, to undertake undergraduate teaching. Candidates should have a higher degree and be actively engaged in research.

Salary on scale £7,221 × 12 increments to £12,087 per annum, inclusive of London Allowance.

Write for further particulars to the Personnel Officer, University of London Goldsmith's College, New Cross, London SE14 6NW. Closing date for applications 28th August 1981. (9272)A

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENTS OF BIOCHEMISTRY AND PATHOLOGY

Applications are invited from graduate biochemists for a temporary post of

JUNIOR RESEARCH ASSOCIATE

to work on the isolation and characterisation of human monocyte antigens. The post is tenable for a period of one year.

Salary will be at an appropriate point on the Range 1B scale: £5,285 to £7,700 pa according to age, qualifications and experience.

Applications, with full curriculum vitae and the names of three referees, should be lodged with Professor R H Pain, Department of Biochemistry, The University, Newcastle upon Tyne NEI 7RU, not later than 28th August 1981. (9279)A

UNIVERSITY COLLEGE, BOTSWANA

Applications are invited for the post of

LECTURER IN GEOMORPHOLOGY

Applicants should hold at least a Masters degree with specialisation in Geomorphology. Those with a PhD will be given preference. An ability to teach Hydrology would also be an advantage. The appointee will be required to teach an introductory course in Physical Geography, and a practical course in map and air photo interpretation at Part I level, and an advanced course in Geomorphology at Part II level. The Department would welcome an appointee with a strong interest in the use of remote sensing techniques in Geomorphological and Land Evaluation. There are excellent opportunities for research in Botswana, and the Department has continuing programmes in Quaternary studies in the Kgalagadi and in land use survey and evaluation related to resource development.

Salary scale: Lecturer P7,212—11,604 pa (£1 sterling = P1.64). The University College has a small number of positions within its establishment for which the British Government provides salary supplementation. The present posts carry no such benefits and are offered on ordinary expatriate terms only. Two-year contract (renewable); contract addition; family passages; baggage allowance; gratuity; assistance with accommodation, hard furniture provided.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent to the Registrar, University College Botswana, Private Bag 0022, Gaborone, Botswana, to arrive no later than 11 September 1981. Applicants resident in UK should also send 1 copy to the Committee for International Cooperation in Higher Education, The British Council, Higher Education Division, 90/91 Tottenham Court Road, London W1P ODT. Further details are available from either address. (9267)A

UNIVERSITY OF BIRMINGHAM Faculty of Medicine and Dentistry DEPARTMENT OF CANCER STUDIES

A RESEARCH FELLOW

with several years' post doctoral experience is required to join a team examining the interactions of virus transforming proteins with cell proteins. Applicants should have experience in protein biochemistry and have a good knowledge of mammalian cell biology. The post is supported by the Cancer Research Campaign. For three years.

Salary research range 1A (£6,070 to £10,575) with superannuation.

Applications (three copies) with full curriculum vitae and the names of two referees to Assistant Registrar, Medical School, Birmingham B15 2TJ by 30 September 1981. Quote reference RF/CS/381. (9282)A

POST DOCTORAL -**RESEARCH POSITION**

for Biochemist-Cell Biologist available September 1, for two to three years, to identify, isolate and characterize insulin-like growth factor and α -thrombin receptors. (J. Biol. Chem. Vol 256: 2767, 1981) from cultured cells and tissues.

Experience in membrane protein chemistry, monoclonal antibody production, and/or ligand receptor characterization is desirable but not essential. \$15,000 to \$20,000 yearly depending on qualifications.

Send curriculum vitae and names of three references to Dr James F Perdue, Lady Davis Institute for Medical Research — Sir Mortimer B Davis — Jewish General Hospital, 3755 Cote St Catherine Road, Montreal, Que Canada H3T 1E2. (NW760)A

UNIVERSITY OF GLASGOW DEPARTMENT OF CHEMISTRY POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Postdoctoral Research Assistant-ship, supported by the Science Research Council, for work on the biosynthesis of pyrrolizidine alkaloids. The appointment will be available for two years from 1st October, 1981, at a salary within the range £6,070 — £6,880 (Range 1A, Research & Analogous Staff scales) with USS benefits.

Applications including a full curriculum vitae and the names of two referees should be sent to Dr Robins, Department of Chemistry, University of Glasgow, Glasgow G12 8QQ.

In reply, please quote Ref. No. 4839. (9260)A

Medical Research Council Centre

Neurochemical Pharmacology Unit

NEUROPHYSIOLOGIST

Applications are invited for this NON-CLINICAL SCIENTIFIC post in an active multidisiciplinary research team investigating the actions of neurotransmitters, neuropeptides and psychoactive drugs in mammalian CNS. The successful candidate will head our neurophysiology laboratories, with modern and well equipped facilities. Applicants should preferably have several years of post-doctoral experience and familiarity with modern neurophysiological techniques, and be available for appointment from around October 1981. The post may be filled by either a SHORT-TERM appointment of 3 (to 5) years or a CAREER (TENURED) appointment according to the age and experience of the successful candidate. A career appointment may subsequently entail changes in a scientist's place of work or field of work.

Remuneration will be at an appropriate point on the scales for university non-clinical academic staff.

Applications in writing within the next four weeks, with CV and names of two professional referees, and quoting reference number NP/3 to: The Administrator, MRC Centre, University Medical School, Hills Road, Cambridge CB2 2QH.

AGRICULTURAL RESEARCH COUNCIL

FOOD RESEARCH INSTITUTE

NUTRITION & FOOD QUALITY DIVISION

Nutritionist

Senior Scientific Officer/Higher Scientific Officer

The Institute has a vacancy for a Nutritionist to take charge of a new group working on the methodology of measuring food and nutrient intake in man. The officer appointed will be responsible to the Head of Division (Dr. D. A. T. Southgate) and will be expected to develop the research programme of the group.

The post calls for an interest in quantitative human nutrition and the problems of assessing food intake of individuals and groups of the population over long periods. An interest in food composition and the application of computer techniques in the assessment of nutrient intakes is essential.

Qualifications: A first or upper second class Honours degree in Nutrition or a related subject with research experienced that has involved studies of measuring food intake in man. At least 2 years relevant post-graduate experience required for HSO; 4 years for SSO grading.

Salary: (under review)

quoting ref. 81/41.

Senior Scientific Officer — on a scale £7,644 — £9,619. Higher Scientific Officer — on a scale £6,075 — £7,999.

Further particulars and application form from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA

Closing date: 31st August 1981.

(9259)A

LIVERPOOL POLYTECHNIC

Department of Chemistry and Biochemistry

RESEARCH ASSISTANT

£3,918 — £4,590 p.a.

Required to work on sweat physiology/biochemistry in relation to cystic fibrosis. The work will mainly involve radioimmunoassay and electrolyte determinations. The project is funded by the Cystic Fibrosis Research Trust and initially is for one year commencing October, 1981.

Applicants should have a first degree in Biochemistry or Physiology. It may be possible for a suitable candidate to register for a higher degree (CNAA).

Further details and applications from Dr. F. McEvoy, Department of Chemistry and Biochemistry, Liverpool Polytechnic, Byrom Street, Liverpool L3 BAF.

Closing date is 21 days from the appearance of this advertisement. The Council is an Equal Opportunity Employer and welcomes applications irrespective of race, sex or marital status.

THE FLINDERS UNIVERSITY OF SOUTH AUSTRALIA SCHOOL OF PHYSICAL SCIENCES

Graduates in chemical engineering, chemistry or physics are invited to apply for the position of

Research Assistant (High Temperature Electrochemist)

The appointment will be initially for one year. Under a grant from ALCOA of Australia Limited a feasibility study will be carried out to measure oxygen concentration in molten fluoride electrolytes using the principles of the Flinders Oxygen Probe. Candidates with a high-temperature-electrochemical background will be preferred.

Salary will be up to A\$15,664 a year, depending on qualifications and experience.

Enquiries regarding this position should be directed to Associate

Professor H J de Bruin, telephone (08) 275 2192 or 275 2111.
Written applications, including curriculum vitae and the names and addresses of three referees, should be lodged with The Registrar, The Flinders University of South Australia, Bedford Park, South Australia, 5042 not later than Friday 28th August 1981

NMR Spectroscopist

A vacancy exists for an NMR Spectroscopist in the Analytical Department of our Pharmaceutical Research Laboratories. The Department is involved in the development and application of methods of measuring drugs in biological fluids as well as the provision of mass spectrometry and NMR services to other departments, notably Synthetic Chemistry and Drug

The ideal candidate will be a young graduate or equivalent with 2-3 years experience of the operation and maintenance of Fourier transform NMR spectrometers and who have some knowledge of the interpretation of data. We expect shortly to take delivery of a Brucker 250 MHz Fourier transform spectrometer and the successful applicant will take charge of this and provide a service to the other departments as outlined above.

The Company is situated at Milton Keynes where housing is available for rent or purchase.

Salary and conditions are of the order to be expected from a world leader in the pharmaceutical field and include contributory pension with free life insurance, membership of PPP and a generous relocation allowance, if appropriate.

Please write or telephone for an application form to: Adrian Forrest, Personnel Department, Hoechst UK Ltd., Walton Manor, Walton, Milton Keynes, Bucks. Tel: Pineham 5068.

(9264)A

Hoechst

UNIVERSITY OF **CALIFORNIA** Los Angeles Tenure Faculty Position ASSOCIATE OR FULL PROFESSOR IN THE FIELD OF PLANETARY **ATMOSPHERES**

A position has become available for a joint appointment in the Department of Atmospheric Sciences and the Institute of Geophysics and Planetary Physics.

Preference will be given to Senior Scientists with recognized accomplishments, whose interests are in global atmospheric composition evolution of planetary atmospheres.

The position will require the successful candidate to develop a strong research program. A moderate teaching load will be expected in the Department of Atmospheric Sciences.

Applicant deadline: 30 November 1981. Please send résumés to Hans Pruppacher, Chairman, Department of Atmospheric Sciences, University of California, Los Angeles, California 90024. An Equal Opportunity/Affirmative Action Employer. (NWX796)A

FELLOWSHIPS

IMPERIAL CANCER **RESEARCH FUND** POSTDOCTORAL RESEARCH **FELLOWSHIP**

Applications are invited for a three year postdoctoral appointment in the joint laboratories of Tumour Virology and Viral Leukaemo-genesis at Lincoln's Inn Fields to apply recombinant DNA techniques to the study of virus-induced oncogenesis. Molecular cloning of RNA tumour viruses is being undertaken to investigate, by a combination of restriction enzyme analysis, DNA sequencing and DNA transfection, the structure and function of mutant and wild type viral transforming genes and their interaction with host cell sequences in which they integrate. Salary range £7,700 - £9,750 plus London Allowance £967 a year, with entry point according to qualifications and experience. Wyke (tel. 01-242 0200 ext 270).

Further information from Dr. John Applications with curriculum vitae and names and addresses of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 by 31st August, 1981 quoting reference (9243)E 124/81

UNIVERSITY OF LEICESTER SCHOOL OF BIOLOGICAL

SCIENCES

ICI/UNIVERSITY JOINT LABORATORY Applications are invited for a POST-DOCTORAL **FELLOWSHIP**

in a group studying the molecular genetics of methylotrophic bacteria.

The post provides an opportunity to use modern bacterial genetics and recombinant DNA techniques to study chromosomal organisation in an industrial micro-organism. Applicants should have postgraduate experience in a relevant discipline, but experience in molecular cloning is not essential.

The salary will be in the research and analogous scale £6,070 — £10,575 and the appointment will initially be for two years.

Applicants should send a curriculum vitae and the names and addresses of two referees to Professor W J Brammar, Department of Biochemistry, University of Leicester, Leicester LE1 7RH, from whom further details can be obtained. (9192)E

UNIVERSITY OF KENT AT CANTERBURY RESEARCH FELLOWSHIPS IN PHYSICS

Applications are invited for two posts of Research Fellow associated with projects involving structural studies of molecular liquids and amorphous solids by diffraction methods. One appointment is for three years for work concerned primarily with the use of pulsed neutrons from the Harwell Electron Linac but some work on the high flux reactor at ILL Grenoble is also envisaged. The second post is available for two years and involves the use of X-rays from the Synchrotron Radiation Source at the Daresbury Laboratory, Cheshire. Both projects, under the supervision of Dr John Dore, will exploit the short wavelength nature of these new sources to obtain detailed information on molecular conformation and orientational correlations. Prior experience with diffraction and computing techniques will be an advantage but is not a prerequisite. Salary range £6,070 — £7,700 on the Grade IA scale.

Application forms and particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Chemical Canterbury, Kent CT2 7NH to whom completed applications should be submitted by 28 August 1981, Please quote ref. A24/81/N. (9256)E

UNIVERSITY OF **BRITISH COLUMBIA**

Vancouver

POSTDOCTORAL RESEARCH FELLOWSHIP IN IMMUNOLOGY

An Immunologist is being sought to join a research group investigating network aspects of the immune system. The salary will be in the range 14,000 dollars to 15,500 dollars (Canadian).

The position is for one year initially, and can be extended up to two years.

Applicants should write to Dr G W Hoffmann, Depts of Microbiology and Physics, UBC, 2075 Westbrook Mall, Vancouver, BC Canada V6T 1W5, and ask two referees to write to (NW803)E him on their behalf.

UNIVERSITY OF DUNDEE **DEPARTMENT OF BIOLOGICAL SCIENCES** POSTDOCTORAL RESEARCH FELLOWSHIP EST/48/81J

Applications are invited for the above post to work with Professor J.A. Raven and Dr. J. Beardall on an investigation of the significance of 'slippage' and protein turnover in the energetics of shade-adapted phototrophs. Appointment from 1 January 1982 for up to three years within the salary range £6,070 — £6,475.

Further particulars from Personnel Office, The University, Dundee Office. DD1 4HN, to whom applications (2 copies) should be sent by Wednesday 30 September 1981 (9262)E

The Izaak Walton Killam **POSTDOCTORAL FELLOWSHIPS**

1982-1983 DALHOUSIE UNIVERSITY

Fellowships valued at \$16,000 (1981-82), plus travel allowances, are tenable for one year at Dalhousie University in most fields of study. Application for extensions may be considered.

Qualification

Applicants should have recently completed a Ph.D. degree at a recognized university, or expect to obtain a degree before taking up an award

Application

Application forms may be obtained by writing

The Office of the Dean Faculty of Graduate Studies Dalhousie University Halifax, Nova Scotia B3H 4H6

The closing date for receipt of applications is 15 December, 1981.

(NW794)E

UNIVERSITY OF EDINBURGH DEPARTMENT OF MOLECULAR BIOLOGY **POSTDOCTORAL**

RESEARCH FELLOW

Applications are invited for a postdoctoral research fellowship in the above Department for work involving the cloning of developmentally regulated MRNA sequences in Xenopus. The appointment available from 1st October 1981 will be for three years on an SERC funded research grant. Salary starting at point 3 (£6,880) on the 1A Range for Research and Analogous Staff. Candidates with directly relevant experience would be preferred, but inquiries are also invited from people who have recently completed PhD work in related fields and would like to, acquire methods of nucleic acid and cloning technology. Informal enquiries may be made to Dr P Ford (031) 667 1081 ext 2873/8.

Applications should be made in writing, quoting at least two referees, to Dr P J Ford, Department of Molecular Biology, King's Buildings, Mayfield Road, Edinburgh EH9 Please quote Reference 5042 (9273)E

UNIVERSITY OF KENT AT **CANTERBURY** RESEARCH FELLOWSHIPS IN PHYSICS

Applications are invited for two posts of Post-Doctoral Research Fellow for a new research programme directed by Dr D A Jackson to develop optical sensors, using lasers and fibre optics, for industrial, surveying and research applications. The programme is funded by the SERC and the Royal Society and the appointment will be for three years. Experience in optics and electronics would be an advantage though not essential and the successful applicants should be prepared to collaborate with potential users of the sensors. Salary will be in the range £6,070 - £8,515 on the Grade 1A

Application forms and particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Chemical Canterbury, Kent CT2 7NH to whom completed applications should be submitted by 28 August 1981. Please quote ref. A25/81/N. (9254)E

IMPERIAL CANCER RESEARCH FUND POSTDOCTORAL RESEARCH **FELLOWSHIP**

Applications are invited for a three year, postdoctoral appointment in the Viral Leukaemogenesis Laboratory at Lincoln's Inn Fields to work on control of expression of membrane proteins during differentiation of erythroblasts transformed by avian retrovirus, in particular avian erythrobalstosis

Salary range: £7,700 to £9,750, plus London Allowance of £967 a year, with entry point according to

qualifications and experience. Further information from Dr. M. Hayman (telephone 01-242 0200 extension 448). Applications including full curriculum vitae and names and addresses of two referees should be sent to the Research Fund, Lincoln's Inn Fields, London WC2, by 31st August, 1981, quoting reference 121/81. (9244)E

GRANTS

UNIVERSITY OF LONDON GRANTS FOR RESEARCH

Applications are invited from members of the University and teachers in Schools of the University for grants from the Central Research Fund to assist specific projects of research and for the provision of special materials and apparatus. Grants are not made for normal maintenance.

Applications must next be received not later than 8 September 1981. Forms of application and further particulars may be obtained from the Secretary to the Central Research Fund, University of London, Senate House, Malet Street WC1E 7HU.

Microcapsules

Diffusion Control in Food Systems Microcarriers for Mammalian Cell Culture Microcarriers in Vaccine Production

Major advances have been witnessed in the past few years in the area of biotechnology, which can be defined as the application of engineering principles to biological processes. In this coloquium, the use of novel concept - microcapsules and microcarriers - in biotechnology will be discussed. These particles possess significant potential in both basic and applied research. The applications in several important areas will also be discussed including their use as (i) supports for cells which make useful products, (ii) matrices for enzymes to be used as bioproducers or bioconverters, and (iii) the central components in drug and food delivery systems. ASSISTANTSHIPS

UNIVERSITY OF EXETER DEPARTMENT OF CHEMISTRY POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a postdoctoral Research Assistantship (supported by the SERC) to work on the metabolism of the branched chain amino acids. The project will include the stereospecific synthesis in isoptopically labelled form of biological intermediates and studies of their conversions into both primary and secondary metabolites.

The appointment will be for two years, commencing 1 October 1981. Salary within the range £6,070 to £6,880 per annum, placement dependent on age and experience. Applications with curriculum vitae, and the names and addresses of two referees, should be sent as soon as possible to Dr D H G Crout, Department of Chemistry, University of Exeter, Stocker Road, Exeter EX4 4OD. (9278)P

UNIVERSITY OF GLASGOW DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited from Organic chemists for a 3 year postdoctoral research assistantship supported by the SRC to study stereochemical aspects of the biosynthesis of some fungal lactones. The initial salary will be within the range £6,070 — £6,880 (Range 1A, Research and Analogous Staff scales).

Applications including curriculum vitae and the names of two referees should be sent to Dr N J McCorkindale, Department of Chemistry, The University, Glasgow G12 8QQ.

In reply please quote Ref. No. 4840. (9261)P

UNIVERSITY OF EXETER DEPARTMENT OF

CHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a post-doctoral Research Assistantship (supported by the SERC) to work on the biosynthesis of riboflavin. Previous experience in the isolation and purification of plant or microbial metabolites in the application of isotopic techniques to the investi-

gation of biological pathways and in

the handling of fungal systems would be an advantage.

The appointment is for two years, commencing 1 October 1981. Salary within the range £6,070 to £6,880 per annum, placement dependent on age and experience. Applications, together with a curriculum vitae and the names and addresses of two referees, should be sent as soon as possible to Dr D H G Crout, Department of Chemistry, University of Exeter, Exeter EX44QD. ASSOCIATESHIPS

National Research Council Canada

Conseil national de recherches Canada

1982 RESEARCH ASSOCIATESHIPS

for research in science and engineering in the following laboratories of the NATIONAL RESEARCH COUNCIL OF CANADA:

Atlantic Research Laboratory
Division of Biological Sciences
Prairie Regional Laboratory
Division of Building Research
Division of Electrical Engineering
Industrial Materials Research Institute
Division of Mechanical Engineering
Division of Chemistry
Herzberg Institute of Astrophysics
Division of Physics

Applicants should have recently acquired a PhD in natural science or a Master degree in an engineering field or expect to obtain the degree before taking up the Associateship.

Associateships are open to nationals of all countries although preference will be given to Canadians.

Research Associates will be offered appointments to the staff of the National Research Council on a term basis and will be offered salaries and benefits currently available to members of the continuing staff.

The initial appointment will normally be for a twoyear term and may be renewed, subject to the Associate's performance and subject to the requirements of the Division. Renewals are considered annually. The term as a Research Associate will vary by Division but will not exceed five years.

An allowance will be provided towards the cost of travel.

Applications may be obtained from the Research Associates Office, National Research Council of Canada, Ottawa, Ontario, Canada, K1A OR6.

Closing date: 15 December 1981. (9253)P.

Aims and Scope

Toxicology is the study of the reactions, both adverse and compensate living creatures to noxious materials. The hazards to which man is exposed and the manner in which he reacts to them from the moment conception and thereafter throughout life is the subject of Human Toxicology. This new journal embraces both animal research, where a direct significance for man, and studies on man himself. These stud may be biochemical, physiological, pathological, clinical and epidemiological but will all be designed to increase our understanding the action of noxious substances in the body and of means to counter effects. All papers will be subject to peer review.

Main Features

The following material will appear on a regular basis:

- * Original papers of a high scientific standard on all aspects of hum toxicology, embracing both animal research and studies with huma
- * Short communications
- * Invited comment on current matters of professional interest
- * Editorials on topical issues
- * Review papers
- * Book reviews

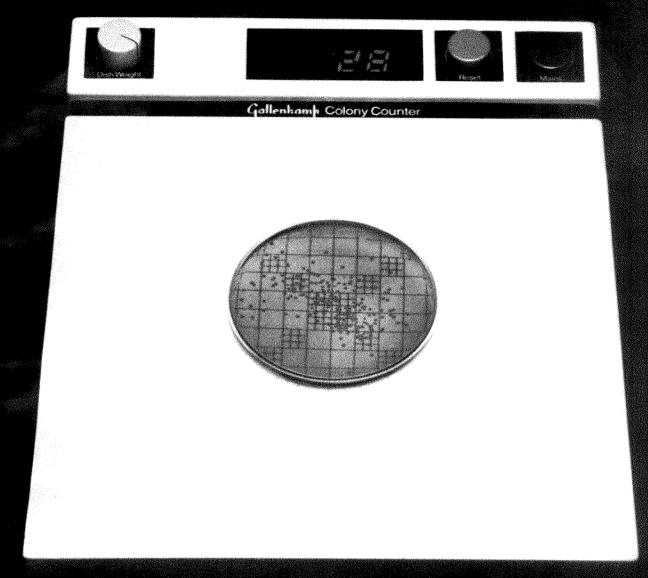

Call for Papers

The submission of suitable papers for editorial consideration is welcompapers must be in English and two copies should be submitted. References, collected at the end of the paper, should include the authorame, year of publication, title of article, title of publication, volume number and first and last page numbers. They should be listed in alphabetical order. A detailed list of *Instructions to Authors* can be obtained from the Publisher. Papers should be sent directly to the Edit Secretary, Human Toxicology, 4 Little Essex Street, London WC2R England, or to Human Toxicology, Nature, Suite 1503, 15 East 26th Street, New York, NY 10010, USA.

Style that counts

We've introduced some remarkable features into our new Colony Counter, each aimed at improving an often ong and unrewarding but very necessary task.

The compact case styling, simple control layout and improved counter trigger system have resulted in a design which reduces fatigue during prolonged counting operations and requires no special probes or markers.

The counter is simply triggered by depressing the Petri dish. An unobtrusive audible tone increases counting peed by giving an immediate indication of each count ction, rendering visual confirmation unnecessary.

Uniform, glare-free illumination of the dish holder ninimizes eye strain and clearly defines even small or incoloured colonies against light or dark backgrounds.

A dishweight sensitivity control is provided to suit ach individual's preferred operating pressure and type or ize of Petri dish. The unit has three other controls omprising a power on/off switch, a manual reset of the igital display and an audible tone on/off switch.

The samples you can analyze with half a bottle of Ampholine

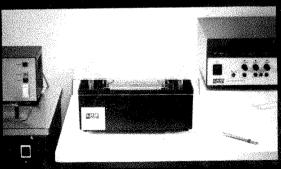

Cut your electrofocusing costs to a fraction of previous levels without sacrificing quality or resolution. Save substantial time casting, running, and staining gels as well. High performance electrofocusing lets you analyze well over 600 samples per bottle of Ampholine. And if you're struggling with an especially tight budget this year, we can help you save even more. High performance gels are cast by capillary action onto thin plastic support foils in layers a mere 0.5 to 0.25 mm thick. Because the new thin gels are cooled more efficiently, resolution-robbing thermal gradients are eliminated while run times drop to as little as 30 minutes.

times drop to as little as 30 minutes.

Ampholine, the LKB tradename for the world's largest selling carrier ampholyte, is now available in four new pH ranges. The new ranges are specially preblended for direct use in either acrylamide or our new agarose gels and exhibit excellent conductivity and reproducibility. By switching

to our new preblends, you'll save preparation time and reduce your stocking costs as well.

High performance electrofocusing is just one of a series of new and improved techniques you can perform on the Multiphor[®] System. For more details about this and other new kits soon to be released, contact your local LKB representative. We have offices everywhere. Or phone us today at one of the addresses listed below.

BIO LOGICALS builds custom oligonucleotides. Faster.

We will ship most custom-synthesized nucleotides within 2-3 weeks of receipt of your order. Our DNA/RNA Synthesizer automates the time-consuming process of building nucleic acid chains and gives results in hours rather than in days.

You can spend more of your time working with nucleotides, less of your time synthesizing them. For cost estimates and to place an order call, write, cable or Telex Margaret Whitby at BIO LOGICALS, Toronto, Canada.

Tel: 416-364-8460 Telex: 06-218746

Cable address: LOGBIO

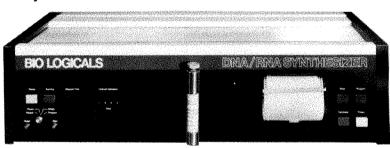

All syntheses

Synthesis

Oligonucleotide sequences of up to 20 bases will usually be shipped within 2-3 weeks of receipt of your order. Modified and labeled bases can be incorporated in custom sequences. We can produce chains of almost any length including entire genes. Speed is not the only advantage of BIO LOGICALS' Custom Service. Our nucleotides are exceptionally pure and our accuracy is guaranteed.

Standard Products

In addition to our custom service our catalogue contains a wide selection of linkers, primers and adapters for immediate delivery. Most synthetic linkers and adapters are available off-the-shelf. Purity and quality are equal to that of our custom products.

The DNA/RNA Synthesizer: in your laboratory or in ours. it will give you the oligonucleotides you need. Fast

DNA/RNA Synthesizer

You may prefer to purchase your own DNA/RNA Synthesizer. If you do your technician will be able to make the nucleic acid sequences you need. Any desired sequence up to 14 bases in length can be built automatically. Each base addition takes approximately 30 minutes. Operation simply involves loading the correct column, connecting our reagent and base packs and programming-in your sequence. The DNA/RNA Synthesizer cycles automatically until the chain is complete. It is then ready for the next program. After removal from the column your sequence may be purified or used as is for certain applications. Ligation of 14-mers is a

How Britain runs its Science

This highly successful wallchart, which first appeared in 1975, has now been completely revised and updated.

The 2×3 ft guide offers a comprehensive survey of the administration of British science. It provides a full account of the funding of science in Britain, giving details of money spent by government, research councils, industry and universities.

Designed as a fold-out sheet, it can be carried easily to meetings or hung as a wall poster for permanent reference. The new 1981 edition is available at £3.50 or \$7.95 by sending your cheque to either Nature's London or New York offices.

In the UK and elsewhere: Nature, 4 Little Essex Street, London WC2R 3LF, England.

In the US and Canada: Nature, Suite 1503, 15 East 26th Street, New York, NY 10010, USA.

GUIDE TO AUTHORS

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). A draft abstract (50 words) is required.

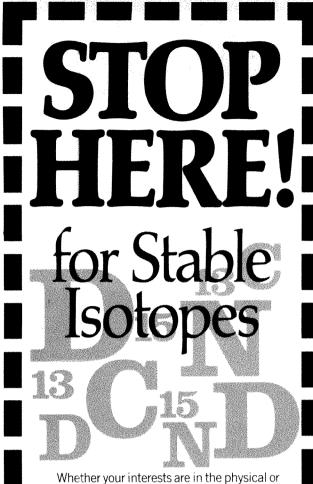

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Whether your interests are in the physical or the life sciences we can supply the stable isotopes you need. As the new agents for KOR Isotopes in the UK our product range includes:

- 35 basic and speciality NMR solvents
- Over 500 Deutirium labelled compounds and reagents
- More than 300 ¹³C and ¹⁵N labelled biochemicals including the widest range of L-Amino Acids tracers available.

Over 100 Gas Chromatography/Mass Spectrometry standards for drug and toxicology monitoring. **KOR**

If you know KCR Isotopes already you will be pleased that we can now

offer a more personal service, but if you haven't heard how we can help you, please write or telephone today for a full product catalogue.

Odd ways with neutron bombs

That President Ronald Reagan has taken the decision on neutron bombs from which his predecessor shrank in 1979 is no great surprise. But the National Security Council's advice last week - with Secretary of State Alexander Haig apparently dissenting — will reverberate for several months to come. Although the Administration's plan is that the neutron weapons, when manufactured, should be stockpiled in the United States and not shipped to Europe, several democratic European governments will find that circumstance of very little help in dealing with their own electors. The only potential battlefield in which neutron weapons might have a place is in Central Europe but there they could be a powerful reinforcement of the tactical nuclear weapons, euphemistically called "theatre weapons", now or soon to be deployed. It is understandable that Mr Reagan should resist the notion that European governments should hold some kind of veto over the munitions policy of the United States, but it is not merely insensitive of him but dangerous to the cohesion of the chief alliance in which the United States is engaged, to behave as if European opinions are irrelevant.

Scepticism about the feasibility and effectiveness of neutron weapons has by now been largely dissipated. If it is possible to make a high-yield thermonuclear weapon by using a fission bomb to detonate a fusion mixture in such a way that the neutrons produced cause fast fission in a casing made of, say, uranium-238, why not play the same trick within a casing of beryllium, so multiplying the yield of neutrons? The only wonder is that something like this can be done within the diameter of eight-inch howitzer shells. And given the penetrating power of energetic neutrons, there is probably something in the claim that neutron weapons would be relatively more damaging than fission weapons to people rather than property - which is not to say that tanks or other battlefield equipment would remain in working order, ready to be turned against their original owners once the dead (and dying) bodies had been removed. So why is there so much opposition in Europe to what seems to be a sensible improvement of military technology?

Part of the reaction against neutron weapons springs from the widespread conviction that, because all nuclear weapons are abominations, the addition of a new design to existing armouries must be a calamity. The argument is mistaken. European defence is for the time being based on the assumption that nuclear weapons would have to be used in a serious conflict, even if the consequence might be the widespread destruction of European life and property. Neutron weapons, less damaging than "ordinary" nuclear weapons and more easily directed against military personnel, should therefore be more acceptable to European opinion. That is the simple counter-argument. It does not fully meet the subtle European complaint that the availability of relatively usable nuclear weapons will encourage their earlier use in any future European conflict. But that argument cuts both ways. The earlier use of comparatively safe nuclear weapons might just as well serve to prevent a more damaging exchange of nuclear weapons at a later stage as to invite early nuclear retaliation. In the bizarre logic of the nuclear battlefield, in which strategic nuclear weapons are intended to stay forever in wonderland, neutron weapons are a blessing and not a curse.

Unfortunately, especially for President Reagan and for those politicians in Western Europe who must now learn to live with last week's decision, this is not the end of the argument. Protests against the manufacture of neutron weapons may be inconsistent with the assumptions on which the defence of Western Europe is

based, but this does not mean that they count for nothing especially at the European ballot box. For the past three years, since Chancellor Helmut Schmidt courageously put his political head on the block by saying that he would allow neutron weapons in West Germany (without foreseeing that President Carter would find it politic to stab him in the back), it has been plain that the wayward trend of the past few years in European opinion will be countered only by a resumption of negotiations between the United States and the Soviet Union on nuclear armaments. These negotiations are, in any case, necessary for other and more compelling reasons, the need in Western Europe to modify strategic stand-off by flexibility in East and West European relations chief among them. In the past few weeks, the United States Secretary of State, followed with a needless show of diffidence by the Administration of which he is a part, has been talking hopefully of a resumption of the negotiations on the Salt II treaty (still in limbo) later in the year. (The diffidence is needless because the Administration has no choice.) Has this brave prospect now disappeared?

The most cynical reading of last week's decision on neutron weapons is that it is not (as Pravda and the Soviet news agency TASS have been saying) a proof that the United States is not serious about negotiations on strategic weapons but, rather, that it is the opposite — a preparation for Mr Haig's promised talks. For what could be more astute than to stake a claim to the right to deploy neutron weapons in Europe so as to increase the range of possible concessions during a negotiation? The trouble is that last week's meeting of the National Security Council — perhaps the most fully reported on record - seems to have been more iconoclast than that. And even if the underlying calculation is machiavellian, it is wrong. While the Netherlands (reluctantly a potential host for United States cruise missiles and Pershing II missiles in 1983 or thereabouts) still lacks a government, with the danger that the democratic and electoral rot might spread (Belgium?) and with the West German defence budget rising less quickly than expected, the United States Administration may find that it cannot hold the ring in Western Europe, even until Mr Haig's target date later in the year, if it fails to reckon with its allies' ballot boxes, not just with its own. That is a penalty of being a superpower, as the Soviet Union has found in Poland.

Stanford's patent prize

Is Stanford University just lucky? Or unlucky? Or do the problems stemming from its exploitation of the Boyer-Cohen patent, which goes to the root of many present attempts to make a commercial success of genetic manipulation, derive simply from its good sense, over several decades, in recruiting faculty members with skill, imagination and flair? The answer is yes on all three counts.

When universities of all kinds are under serious financial pressures, one that finds itself blessed with what may be a substantial source of revenue in the 1980s (until the patent runs out) will be the envy of both private and public universities in the United States and elsewhere. Even so, it is unlikely that Stanford would have sought the invidious position of being the first university in the United States to have patented a scientific discovery that is already of outstanding importance in research laboratories (where patent protection entails no restriction) and may yet be the basis of a new industry.

Stanford's patent has been made possible by the changes of policy nearly a decade ago at the National Institutes of Health, which made it possible for universities to apply for their own patents even when financial support had come from federal funds. (One irony in the case of the Boyer-Cohen patent is that the University of California never succeeded in negotiating what is called an Institutional Patent Agreement, whence its partnership with Stanford in this venture.) Last year, the doctrine that recipients of federal research grants may nevertheless patent discoveries that arise, and not leave them in the public domain. was extended by the new patent legislation to most agencies of the federal government. The arrangement has some virtues. It provides universities with an independent source of income, and there is a chance that some universities will be more efficient merchants of innovation than the government has been. Given its traditions, Stanford could hardly have stood aside from these developments. In that sense, its bad luck has been thrust upon it.

The university and its members have in the circumstances conducted themselves with the utmost propriety. First, the authors of the discovery have assigned all their personal rights to their respective universities, and will make no financial gain from whatever happens in the next few years. Second, Stanford has apparently consulted widely with the companies likely to be the first in the field with practical applications of the new techniques. Third, patent protection has apparently not been sought outside the United States (but less liberal regulations on prior publication elsewhere might have been an obstacle). Fourth, the terms to would-be licensees are modest, as these things go; neither university seems out to make a quick buck, or an unseemly number of bucks. Even the imminence of the deadline (15 December) before the terms are made stiffer is forgivable, given the advance consultation there has been. And licensees will have to comply with National Institutes of Health guidelines. Finally, Stanford stands out among universities in the United States in having formulated an explicit policy for the seemly division of the spoils from patent exploitation between the university, the inventors and the departments to which they belong (see Nature 18 June, p.524); the Stanford faculty will be debating these proposals early in the new academic year.

So why should there be a fuss, if fuss there is? Most probably the commercial companies, especially those which Stanford has consulted in advance, will take out licences promptly and without complaining that they are being held to ransom. They will know that it will cost them more to buy exclusive (as distinct from nonexclusive) licences for particular applications of genetic manipulation from the genetic engineering companies that have mushroomed in the past few years. Even so, a legal challenge to the patent is more than possible if less than probable, either on the grounds that Boyer and Cohen were not the only authors of the research or that, in the early 1970s, the techniques now patented were not as novel as they may have seemed. Stanford seems prepared for such a challenge (see page 573) and may well be right in thinking that it would win its case. What will concern its friends, those who admire and owe an intellectual debt to Boyer and Cohen as well as those concerned for the reputation of scientific scholarship, is that a wrangle about scientific priority in the courts would be damaging to institutions and people.

Another difficulty goes to the root of current policy in the United States on the exploitation of federally sponsored inventions. There is now a danger that, in the years ahead, drafts of papers for publication will be read with an eye not merely for scientific merit but for exploitability. Moreover, Stanford and the University of California at San Francisco apart, it remains to be seen whether the federal government's new liberality on patents will turn out to be a golden goose or merely another addition to the cost of university administration. A more serious problem is that most universities, within and outside the United States, still lack policies for deciding how the commercial benefits of invention should be divided internally among the interested parties; one obstacle is that the financial interests of the faculty are in many cases already too deeply entrenched. The danger now is that the commercialization of academic work will be reinforced

- and that the benefits will be spread throughout the university system more or less at random, according to the chance that some discoveries will be patentable and others not.

Although in the short run some universities may benefit, all must know that precarious income from patents is no basis for running a university system. Worse, they must also fear that the further they go along the money-making path, the harder it will be for all of them to stick to their proper tasks of teaching and scholarship. And while it may be pleasing to be able to demonstrate to governments that universities can turn their hands to business when they are pushed, that proposition conceals a trap. For the universities have always contributed to socially and commercially valuable innovations. If they now accept the notion that they can do so effectively only when they are rewarded, their place in public esteem will be diminished.

Polytechnics in passing

Once upon a time, when there seemed no limit to the growing demand for higher education in the United Kingdom, the late Mr Antony Crosland, in his capacity of Secretary of State for Education and Science, wove a marvellous spell. In a speech at Woolwich fifteen years ago, Mr Crosland brought into being an entirely novel system of higher education, which he called the "binary" system. One half consisted of the traditional universities. The spearhead of the other half was to be 26 technical colleges, which were redesignated as "polytechnics", urged to provide degree courses for their students (which many already did) but to concentrate on practical things such as engineering, technology, business - the "world of work" as it has since been called. In a curious way, Mr Crosland's magic wand marked the beginning of the universities' fall from grace. If the "other" half was to be the provider of practical higher education, how could the universities fail to be thought effete? But now it is the polytechnics' turn to take a tumble.

After two years of blustering, the British government has now issued a discussion document that will spread gloom and despondency in the polytechnics — and among the local authorities which are their titular sponsors (Higher education in England outside the universities: policy, funding and management: Department of Education and Science). The government's supporters, if they have the time to read such a specialized document, may also take fright. For the government now seeks to set up some kind of central body to supervise working of "higher education outside the universities". The local authorities know they have no ground on which to stand — the cheques they write each month to pay the salaries of teachers in polytechnics are immediately discounted by the central government. Worse still, there is a suspicion that the local authorities which happen to be the channels of the central government's cash flow towards the polytechnics (now grown in number to 29) would put higher education high among their priorities. There are cheaper ways of catching votes and, in any case, local authorities are probably as disappointed as the rest of the United Kingdom that the performance of the polytechnics has been so disappointing. Those which have chosen not to ape the universities have all too trendily destroyed their claims to intellectual respectability. There are some exceptions.

The government's solution, modestly called "Model B" in the discussion document, is that the polytechnics (and the rest of nonuniversity higher education) should be controlled by a body analogous to the University Grants Committee. The local authorities have lamely countered with what is called "Model A" a scheme in which their representatives will call the shots. Everybody knows how the consultation will be resolved. The government's supporters (if they had the time) would be horrified to learn that the crucial argument is the case (spelled out) that central planning of higher education is not merely necessary but possible. For some time yet, it will be forgotten that the most immediate need is to bring the two halves of the binary system into

some kind of coordination.

Stanford ready to fight for patent

No challenge as yet in sight

Washington

Officials at Stanford University's Office of Technology Licensing are bracing themselves to meet possible challenges to the patent on the set of basic genetic engineering techniques, used to replicate foreign genes in microorganisms, which was offered for licensing last week.

The patent was awarded last December covering the results of research by Dr Stanley Cohen, of Stanford Medical School's departments of medicine and genetics, and Dr Herbert Boyer of the University of California at San Francisco. Stanford is confident that it can successfully resist any challenge, if necessary in court; but patent attorneys in several large companies are already poring closely over the scientific literature in case they decide to question the basis on which the patent was awarded.

The key question is whether these companies are prepared to accept the terms of the Stanford licence. The university is asking for an initial non-exclusive licence fee of \$10,000 and an annual fee of the same amount for the use of the techniques in research. (University scientists will be exempt.) Royalties on product sales will vary from 1 per cent for the first \$5 million, to 0.5 per cent for sales over \$10 million.

Before deciding on these terms, which are relatively low for patent agreements although these usually offer exclusive licensing rights, the university had consulted several companies — including Eli Lilly, Upjohn, Smith-Kline, Schering-Pough, Du Pont and Monsanto — to gauge their reaction to early drafts.

Several have already indicated that they are prepared to accept Stanford's terms. Dr Peter Farley, for example, president of the Berkeley-based Cetus Corporation, said last week he thought the terms were "very reasonable" and that he expected his company to accept them. Similarly Genentech, of which Dr Boyer is a cofounder, has also indicated that it is likely to agree to the terms.

Other companies, however, are refusing to commit themselves — at least in public — until they have studied the implications of the licensing agreement more closely. Patent attorneys for several large pharmaceutical companies said last week that it was too soon to comment on the actions they may take.

Privately there are rumours that at least one company may decide to challenge the patent in court. But company officials list a number of factors they will have to take into account.

One is the public impact of a major court case that could rekindle debate on the ethics and safety of genetic engineering. There is also uncertainty over how much sympathy there would be for a company which appeared to be preventing the two universities profiting from discoveries made in their laboratories. (Both Drs Cohen and Boyer have assigned any personal interest in the royalties to their support teaching and research.)

Against this there is the argument put forward by the president of one small company that, since royalty payments will push up product costs — even if only marginally — the taxpayer wil be paying twice for the same research.

The principal determinant of whether a challenge is filed, however, is likely to be the cost. Each company must calculate whether the amount of money it could save by not paying Stanford the licence fee and royalties would exceed the amount required to challenge the patent successfully.

According to patent attorneys, any such challenge could take one of two principal forms. A company (or group of companies) could seek a court ruling that the patent had been improperly granted. Or — perhaps more likely — a company could continue to use the recombinant DNA techniques without a licence from

Stanford, waiting for the university to sue for the infringement of patent rights.

In either case there are two likely ways in which the Patent Office's decision to issue the patent might be challenged. The first would be to claim that the research results described in the patent were not "novel" since they were already being used by other scientists, and should therefore be considered part of the so-called "prior art". Alternatively, they could argue that the applicants had failed to show that the particular combination of techniques which they describe for the replication and expression of exogenous genes in microorganisms met the legal criterion of being "non-obvious".

Having granted the patent, the patent examiner responsible must have been convinced that the process described met both of these criteria. However, such a judgement is based largely on the material presented to the Patent Office to support the claim, which was filed by the two universities on behalf of Drs Cohen and Boyer.

A challenge on these grounds would not be a surprise. But officials at Stanford are confident that, although many scientists were involved in the discoveries and developments that laid the basic groundwork, they can demonstrate that scientific collaboration between Cohen and Boyer was sufficiently crucial to justify the claims to the patent.

David Dickson

Antecedents of Cohen-Boyer patent

The text of the Boyer-Cohen patent is a nice bibliography of the early history of genetic manipulation between 1972 and 1974. The patent, granted on 2 December 1980, was filed on 4 January 1980 and partly replaces three previous patent applications filed in 1974, 1976 and 1978.

The abstract of the patent says that "method and composition are provided for the replication of exogenous genes in microorganisms", and refers to the use of either plasmid or virus DNA as replicating elements into which foreign genes can be deliberately inserted for later replication and expression. "The method provides a convenient and efficient way of introducing genetic capability into microorganisms for the production of nucleic acids and proteins, such as medically or commercially important enzymes", and the abstract goes on to list possible applications in the production of drugs, the fixation of nitrogen, fermentation, the "utilisation of specific feedstocks, and the like".

The patent says that the process now protected includes the three steps in the preparation of recombinant plasmids, their use for the transformation of bacteria and the replication and transcription of the recombinant plasmids in transformed

bacteria. In its description of the "prior art" the patent lists a series of papers in *Proc. natn. Acad. Sci. U.S.A.* including those by Cohen et al. (69, 2110; 1972), Cohen et al. (70, 1293; 1973), Cohen et al. (71, 1030; 1974), Morrow et al. (71, 1743; 1974) and Jackson et al. (69, 2904; 1972). In addition, the patent cites the paper by Novick in *Bact. Rev.* (33, 210; 1969).

On the preparation of recombinant plasmids, the patent points to the need for preserving the site of replication and to the convenience of some "phenotypical property" that will aid the selection of transformants. Bacteria are mentioned simply as the most convenient of unicellular organisms with which to work, while usable plasmids are said to range in molecular weight from 1 to 50 million daltons. The plasmid pSC101 (developed in 1972 by Cohen et al.) is mentioned as a convenient plasmid for cloning purposes, while the techniques of cleaving plasmid DNA and its subsequent ligation to other pieces of DNA are also described.

Acknowledging that some recombinant plasmids can arise naturally, the patent says that the techniques covered make possible the construction of artificial recombinants, including those between bacteria "which do not exchange information naturally" and between bacteria and eukaryotic organisms "which cannot naturally occur".

The patent says that the techniques can be used with genes to form other bacterial cells, mammalian cells, plant cells and so on. The cloning of multiple genes is mentioned and the production of multiple copies of peptide hormones said to be of especial importance in the cases of parathyroid hormone, growth hormone, gonadotropin, insulin, ACTH, somatostatin and prolactin. Other useful products of genetic manipulation listed

Europe waits to see

European pharmaceutical companies have reacted cautiously to the announcement by Stanford University that licences on the Boyer-Cohen patent are now for sale. But many of them are huddled with their patent lawyers.

Under the terms of US patent law, companies outside the United States will be obliged to apply for licences only if they intend to market within the United States products made with techniques covered by the patent. Because most European companies are anxious not to foreclose future markets, however, they face the same dilemma as US companies in deciding whether to pay the licence fee and subsequent royalties.

Most companies this week were unwilling to guess what they may in the end decide to do, although it seems that some of them have already been consulted (through their American subsidiaries) by Stanford. Some point out that Stanford's advertised terms are reasonable, but also say that the university has been well advised in fixing a low fee and royalty rate for a non-exclusive licence to exploit a patent as general as Boyer-Cohen. Larger proprietary costs will accrue, they say, when the time comes to buy an exclusive licence to use a more specialized technique from one of the companies set up in the past few years to carry out research and development in genetic engineering.

Some legal anomalies stand out. Will, for example, a European manufacturer that seeks to market in the United States a product made by a process developed by a non-American genetic engineering company itself be required to pay a royalty, or will the legal obligation fall on the company that carried out the research and development?

In the circumstances, three options are being considered: to ignore the licence and face Stanford when products are placed on the US market; to challenge the patent; or simply to pay up. European companies, however, are unlikely to initiate direct challenges, preferring to wait and see what happens in the United States.

Judy Redfearn

include serum proteins, ferritin, myoglobin, interferin (sic), kinins and transcortin.

While illustrating the claims made with specific examples, the patent says that "it is obvious that certain changes and modifications may be practised" within its scope. Among the specific claims are for the ligation both of blunt-ended and "staggered" DNA molecules, to form recombinant plasmids.

On the face of things, the patent would seem not to cover the use of vehicles other than plasmids for the cloning of DNA, so that techniques of genetic manipulation involving the use of animal virus grown on susceptible cells in tissue culture would seem not to be protected. Nor is the development of cloning vectors able to switch between eukaryotic and prokaryotic cells. Yeasts are, however, mentioned.

The patent makes no claim to protection for organisms or plasmids with particular properties, presumably because it was not known whether organisms could be patented until the Supreme Court decided earlier this year in favour of a patent application on behalf of Dr A.M. Chakrabarty by the General Electric Company for a strain of *Pseudomonas* designed for digesting oil spills. Stanford is apparently waiting to hear whether its applications for protection for specific bacterial cloning strains will be successful.

Soviet biotechnology

Further resolve

Soviet progress in biotechnology is being hampered by shortages of reagents and apparatus, and delays in the construction of new facilities. Experiments are limited in scale, and too little is being done to implement theoretical results.

This is the tenor of last month's resolution of the Central Committee of the Party and the Council of Ministers on the further development of biotechnology. The official Soviet commitment to biotechnology began suddenly in May 1974 with a similar resolution, which in effect gave biotechnology priority status and funding from then rather than from the start of the succeeding five-year plan.

Reviewing progress in the past seven years, the Central Committee and Council of Ministers last month noted that the 1974 resolution had introduced "radical changes" in the biological sciences, especially in molecular biology, bioorganic chemistry, molecular genetics and immunology. Research cadres had been trained within a very short time, and in several fields Soviet scientists had attained a "leading position in world science". Despite high hopes, a flourishing biotechnology industry had not materialized.

The resolution suggests, however, that this is not simply because of the difficulty of turning research results into practice. The resolution charges the Academy of Sciences, the State Committee for Science and Technology, the State Planning Committee (Gosplan) and the governments of the union republics with the task of ensuring the conditions for these results to be introduced in agriculture, medicine and industry. But it also calls for intensified fundamental research both directly within the framework of the Academy of Sciences, and the ministries.

The State Committee for Science and Technology, the Academy of Sciences and Gosplan are to adopt a special target-orientated research programme in biotechnology, which will be coordinated by the State Committee's special council on biotechnology and the academy.

The supply problem remains. The resolution merely says that means of ensuring supplies of equipment, reagents, "biochemical preparations", computer technology and an information base in biology and biotechnology have been "noted", but makes no suggestion of what form these measures are to take. Vera Rich

US air pollution

Reagan retreats

Washington

Unexpectedly strong opposition has forced the Reagan Administration to retreat from plans to seek sweeping changes in US air pollution legislation. Initially Mr Reagan had announced his intention to demand a substantial weakening of the Clean Air Act when it comes up for renewal by Congress next month; but following objections not only from environmentalist groups and Democratic congressmen, but also from several leading members of the Republicandominated Senate, the Administration said last week that it was looking for more modest amendments.

One of the most significant shifts in the Administration's position has been its decision to continue to use health standards and "sound scientific data", rather than economic costs, as the basic principle for determining how air pollution should be regulated. Mr Reagan's budget director, Mr David Stockman, as well as members of his Council of Economic Advisors and outside industrial groups, had strongly urged that cost-benefit techniques be added to the statutory requirements of the Clean Air Act, first passed by Congress in 1970.

However, Mrs Anne M. Gorsuch, the new administrator of the Environmental Agency, announced last week that the Administration did not intend to go far down this particular path. Listing the basic principles to be followed in developing legislation to extend the act, she said that "cost-benefit analysis should not be included as statutory criteria in setting these standards", but that standards "should be based on sound scientific data demonstrating where air quality represents

real health risks".

Both supporters and critics of the Administration agree that the concept of "real health risks" will now become the central focus of debate over new regulations — and that the decision may reflect recent rulings by the US Supreme Court which, while denying that costbenefit calculations need be used in setting standards, have also emphasized the legal importance of scientific or epidemiological evidence of existing levels of risks.

Several of the principals announced by Mrs Gorsuch have pleased industry. For example, emission restrictions for nitrous oxides on new cars wil be eased. Under present legislation, all cars produced from this year onwards are allowed to produce only one gramme of nitrous oxide for every mile travelled. The Environmental Protection Agency intends to raise this limit to two grammes, the level at which it stood between 1977 and 1980 and a move which it is claimed could save \$100 on the price of a family car.

There will also be a relaxation in a particularly controversial section of the present legislation aimed at preventing the "significant deterioration" of air quality, even in areas where present levels of pollution are relatively low. This provision stems from a legal interpretation of the 1970 Act following court cases brought up by several large environmental groups; it hass been bitterly contested by industry on the grounds that it restricts the growth of new industries outside existing urban areas.

Mrs Gorsuch said last week that the present programme for the prevention of significant air quality deterioration "should be maintained for the protection of park and wilderness areas". She said that protection in other areas should be based on uniform technology requirements for pollution control.

The Environmental Protection Agency has also committed itself to asking for more funds from Congress for acid rain research. This has recently become a major source of conflict between the United States and Canada, which has accused Washington of failing to comply with an agreement signed last August to reduce air pollution from automobiles and large coalburning facilities. The Administration, with the utilities industry, is now arguing that considerably more research is required before the need for clear action is demonstrated, a position which is unlikely to be warmly greeted in Ottawa.

Critics of the Administration's earlier proposals, contained in draft legislation leaked to the press by congressional Democrats in May, have been given other concessions. Senator Robert T. Stafford of Vermont, for example, insisted that no change should be made to the principle that the young, the elderly and other high-risk groups should be given an extra margin of protection from the effects of polluted air. Furthermore, pollution standards will continue to be set at the federal level and

not, as industrial groups hoping for a more sympathetic hearing had asked, by individual states.

The Reagan Administration's decision to limit its proposed changes seems largely based on a realization that, unlike the cuts in public spending and taxation, there is no national consensus on the need for a major retreat on environmental protection. White House officials are said to have been concerned about the impact of recent aggressive anti-environmentalist statements by Interior Secretary James Watt, and have asked him to adopt a more conciliatory attitude.

But if the battle over the Clean Air Act extension is not going to be as fierce as once promised, it will still be heated. The National Clean Air Coalition claim that even the Administration's more limited proposals are a "blueprint for destruction" of the present laws. Mrs Gorsuch says that, even with the suggested changes, the quality of the nation's air will improve, but "at a more reasoned pace". Congressional hearings will begin next month.

David Dickson

Science jobs famine

Bangalore

Nearly three million scientists in India are unemployed and an equal number are working in posts requiring much lower qualifications, for lower pay than a government clerk receives. These were among the worrying facts which came to light at a recent meeting of the Science Advisory Committee of the Union Cabinet, headed by Planning Commission member and agricultural scientist Dr M. S. Swaminathan, and held to discuss ways of making the best use of the country's science and technology personnel, particularly those unemployed.

For instance, more than 50 per cent of scientists and engineers employed at the prestigious Bhabha Atomic Research Centre draw a monthly salary of less than \$75. And nearly 25 per cent of the personnel working in government-sponsored research and development institutions have a monthly pay packet of less than \$120. However, people working in science and technology in the private sector are better off, seven per cent of them earning \$200 a month.

According to a note circulated to members of the committee, unless the annual rate of industrial growth rises to four per cent there is little prospect of speeding up the absorption of unemployed science and technology personnel into jobs.

The note further recommends regulation of intake of such personnel for training, more informal education, facilities for improving qualifications while on the job and greater interaction between industrial and academic scientists.

B. Radhakrishna Rao

Industrial noise

Let them hear

Britain's Health and Safety Commission is tackling the difficult business of regulating noise at work. Last week it published draft regulations in a consultative document intended to pave the way for legislation which will place a statutory obligation on employers to protect workers from noise. A voluntary code of practice, drawn up in 1972, is being widely ignored, according to the commission.

Devising effective legislation is, however, proving controversial — noise regulations are notoriously difficult to enforce and statutory levels of noise are fiercely disputed. The consultative document proposes limits of no more than 90 decibels(A) — a weighted decibel unit discounting inaudible frequencies — averaged over an eight-hour day and no more than 600 pascals of peak sound pressure. But the trades unions, in particular, argue that as hearing damage can occur at lower levels, the daily average limit should be set initially at 85 dB(A) and later lowered to 80 dB(A).

The number of British workers exposed to high noise levels is considerable. The commission estimates that 50 per cent of production workers (about 2.5 million people) are exposed to more than 80 dB(A) and 10 per cent (500,000 people) to more than 90 dB(A). Nobody seems to have disputed the effect of noise on hearing since the late 1960s. Using the work of Burns and Robinson, the commission estimates that roughly 32 per cent of people exposed to 100 dB(A) over a working lifetime will suffer a 50 dB hearing loss by the age of 65.

The commission has settled for the 90 dB(A) limit on the basis that the hearing of 21 per cent of workers previously exposed to more than 100 dB(A) will be protected. Reducing the limit to 80 dB(A) would save the hearing of only a further 8 per cent. Clearly acknowledging the problems of reducing noise, it argues that a 90 dB(A) limit will give greater benefit for cost.

Under the commission's proposals, however, employers would not be freed from obligations even at lower noise levels. The draft regulations require that they reduce any noise likely to damage hearing to the "lowest level reasonably practicable", which they would have to work out for themselves. Employers fear that this general but unspecific obligation may expose them to civil suits from all those who suffer from hearing loss.

The draft regulations require that at noise levels above 90 dB(A) employers must survey noise, train staff, keep exposure records and appoint a qualified noise adviser. Workers exposed to 105 dB(A) would have to receive regular hearing checks. The proposed regulations also oblige employees to make full use of noise control measures and manufacturers to reduce noise levels of industrial

machinery to below 84 dB(A) if possible. The commission has no estimate of the cost of its proposal.

On this occasion, Britain's Health and Safety Commission seems to be a step ahead of the European Commission, whose directive is still some way off. But the signs are that Europe will go for a limit of 85 dB(A).

Bulgarian astrophysics

Cosmic celebrations

The "Interkosmos-Bulgaria-1300" satellite, Bulgaria's cosmic celebration of 1,300 years of statehood, was launched last Friday (7 August) to the surprise of the Bulgarian public, who had expected it would form the climax of the celebrations in October.

The designation of the satellite was equally unexpected — although the original plan was for a single celebratory satellite, analogous to the Polish Interkosmos-Kopernik-500 in 1972, it was announced earlier this year that there would be two satellites, one containing Bulgarian experiments only and the other a mixed Soviet and Bulgarian payload. However, only in the Moscow radio coverage of last Friday's launch was it made clear that the mixed payload was already in orbit — aboard the Priroda-Meteor satellite launched on 10 July.

In the Bulgarian celebrations, the timing has proved unfortunate, since the head of the jubilee committee, Lyudmila Zhivkova (the daughter of First Secretary Todor Zhivkov) died suddenly on 20 July.

Scientifically, however, the satellite is operating well, and has done much to offset Bulgarian disappointment that the Interkosmos manned programme did not allow them a second chance of a cosmonaut aboard a Salyut craft. By way of consolation, Georgi Ivanov, whose Soyuz transporter failed to achieve a linkup with Salyut, was invited to attend the launch and spoke warmly of Soviet-Bulgarian cooperation.

Although the experiments on the satellite (a modified "Meteor" meteorological probe) are said to have been produced "with the assistance of Soviet scientists", the twelve experiments comprising the 350-kg payload are of Bulgarian design, and concentrate on those branches of space physics of particular interest to the Bulgarian space team, including plasma, high energy charged particle studies, atmospheric luminescence and magnetosphere studies. According to Dr Kiril Serafimov, chairman of the Bulgarian Space Research Council, a special study will be made of ionosphere troughs and equatorial anomalies in the magnetosphere, which it is hoped will provide valuable data for such applied fields as radio-wave propagation, the mechanism of rare meteorological anomalies and the radiation balance of the Earth. Vera Rich

Carcinogenicity testing

Well, yes and no

Washington

Semantic juggling has allowed US health officials to escape the embarrassment of discovering two reports on the widely-used chemical dimethyl terephthalate (DMT) which are virtually identical but contain directly conflicting conclusions about its carcinogenicity.

Re-examination of the test data has raised a dilemma for scientists with the Department of Health and Human Services' National Toxicology Program (NTP) that is frequently faced by regulatory agencies: how to present policymakers with the results of ambiguous animal tests.

The solution proposed by NTP's peer review committee is to describe data on increased cancer rates in male mice as being "statistically significant" but "biologically equivocal".

DMT is widely used to provide flexibility in plastic products from food wrapping to bottles. The source of the confusion is a technical report on its potential carcinogenicity prepared in the 1970s for the now-defunct Clearinghouse on Environmental Carcinogens of the National Cancer Institute (NCI).

The tests were carried out by a private contractor, Hazleton Laboratories. They revealed no evidence of increased cancer rates among male and female rats, or among female mice exposed to low or high doses of DMT. However, a 27 per cent incidence of lung tumours was found among male mice receiving the high doses, considerably higher than the 4 per cent incidence in a group of matched controls. On the basis of these data, which were approved by an NCI peer review group, a report was published describing DMT as a carcinogen in male mice.

Soon afterwards, however, the report was challenged by scientists working with Hercules Incorporated, a major manufacturer of DMT. They claimed that the relatively low incidence of lung tumours among the matched controls was out of line with results from other control groups. NCI scientists reassessed the Hazleton data, this time using for comparison not the matched control group, but pooled results from three other control groups associated with different experiments which had spent overlapping periods of time in the same room. The latter groups revealed a lung tumour incidence of between 10 and 18 per cent over a two-year period, much closer to the 27 per cent of the exposed group.

A revised version of the technical report was subsequently issued through the National Technical Information Service (this time without peer review) which stated in the summary that the new data indicated that DMT was not a carcinogen.

Several research libraries, however, still

have copies of the first version on their shelves. And the apparent discrepancy between the two reports was brought to the attention of NTP, which has taken on the responsibilities of the NCI clearinghouse, three months ago.

Re-examination of the data revealed that the tests appeared to have been properly conducted, even though the incidence of tumours in the matched controls seemed inordinately low. "We view the incidences of total lung tumours in the matched male controls with some suspicion" reported Dr John Moore, deputy director of NTP.

A report on the NTP staff review was brought before the peer review panel of the programme's board of scientific counsellors last month. Discussion soon focused on whether, in revising the original report, the NCI staff had been correct in ignoring the matched control data and

One more journal

A new scientific journal is to be launched at the beginning of 1982 by the European Molecular Biology Organisation (EMBO). One of the objectives of *The EMBO Journal* is to redress the balance between Europe and the United States where, it is argued, the predominant and preeminent position won by American journals in the publication of molecular biology has put European molecular biologists at a disadvantage.

The new journal, which has been in the air for the past three years, was finally agreed after a ballot of the 500 members of the organization held in January. The journal will resemble Proceedings of the National Academy of Sciences of the United States of America in that it will publish papers communicated by any of its members, each of whom will be rationed to a maximum of five papers a year by non-members of the organization.

A statement by the publishers of the new journal, IRL Press Limited of Oxford, England, says that EMBO members will be expected to take responsibility for the "scientific standard" of the papers they communicate. One of the obvious difficulties will stem from the heterogeneity of the membership, which is elected, and the differing interpretation of what molecular biology consists of in various European countries.

The editor of *The EMBO Journal* will be Dr John Tooze, executive secretary of EMBO and also, at present, the editor of *Trends in Biochemical Sciences*. One feature of the new journal is said to be speed of publication — the publishers have undertaken to print manuscripts accepted by the editor within twelve weeks of their receipt. A pilot issue of the journal is to be made available in September.

basing their reassessment on the three other control groups; or whether all four groups should have been pooled into a single set of controls.

Various members of the committee expressed unease with the statistician's technique of ignoring so-called "outsider" data points which did not appear consistent with the other data being evaluated — but which, according to the biologists, there might be no particularly good scientific reason to disregard.

Members of the NTP peer review committee agreed to recommend the aggregate data as the basis of the evaluation about carcinogenicity. But it left the problem of deciding how to describe evidence that was in Dr Moore's words, "something between equivocal and positive".

The proposed solution was an appendix to the second version of the technical report, which will give details of the new analysis and point out that, statistically, the raised incidence of lung tumours in mice exposed to DMT is "highly significant". But the appendix will add that the results are also biologically equivocal — in other words the data do not provide clear evidence on whether DMT is a carcinogen.

The next step rests with the Food and Drug Administration's Bureau of Foods. Previously the bureau's cancer assessment committee had decided, on the strength of the NCI report, that no action was needed against DMT. With the new interpretation from NTP, the committee will have to reassess its position.

Meanwhile the NTP's board of scientific counsellors is meeting soon to discuss whether a more rigorous system of classification, possibly based on procedures developed by the International Agency for Research on Cancer in France, should be adopted in the United States. The DMT episode will encourage their efforts in this direction.

David Dickson

Alternative energy

Enter the Nibe

Brussels

By 1995, about 15 per cent of Denmark's electricity requirements will be met by wind power — if the Danish Ministry of Environment goes through with its plan to plant 3,000 windmills across the country. The plan is being seriously considered and has now been passed to the relevant regional and local authorities for their views.

Denmark is more dependent on imported energy than most other industrialized countries, having to provide 95 per cent of primary energy from outside sources. The only domestic form of primary energy is natural gas under the North Sea, and this will not start flowing until 1984. So research into renewable energy sources has been given high priority.

Even before the last government plan, a 1979 law provided government subsidies of up to 30 per cent of the cost of small

domestic windmills. These have to be of an approved type, and the electricity utility companies are prepared to buy any surplus electricity from the owner.

The new plan is altogether more ambitious. The 630 kW three-blade rotor mills, called Nibe wind turbines, were developed under the 1977–80 wind energy research programme which cost Dkr 39 million (\$7.2 million). The Nibe windmills are raised on a 41-metre concrete tower and the span across the turbine blades is about 40 metres. The mills will operate in wind speeds of between 21 and 90 kilometres per hour. The research programme has evidently ironed out most of the major technical problems, leaving the economic and environmental issues to be debated.

Denmark is a small, densely populated country, so the choice of suitable sites is severely limited. The windmills cannot be placed in areas where they would interfere with recreational, agricultural or other economic interests. If it were possible to find coastal sites for all 3,000 mills, electricity production would be 25 per cent greater than if they were all inland.

Somewhat surprisingly, there is evidence to show a relationship between electricity demand and high winds in Denmark. Apparently heating requirements are greater the stronger the wind blows and, conveniently, this would be countered by more power from the windmills.

But before the windmill ideas take off, it will be necessary to bring down the unit cost of construction — or the other sources of electricity will have become prohibitively expensive. Present cost of windgenerated electricity is \$2,000 per kW of installed power.

As with nuclear power stations, however, there may be objections from local residents. Anyone living near one of these Nibe wind turbines would have to put up with noise, interference with radio and television, and landscape eyesores. But Danish public opinion is likely to favour wind power and Denmark seems likely to be the first country to launch a major commercial wind power programme.

Jasper Becker

India in space

Apple limps on

New Delhi

Although still operating on power from only one if its two solar panels, India's experimental 'Apple'' communications satellite has now been successfully placed into geostationary orbit 36,000 kilometres above Sumatra in Indonesia. Apple's solid-fuelled apogee boost motor was fired on 22 June to achieve near-geosynchronous orbit but one of the solar panels failed to respond to radio commands and did not open. Despite this the satellite was stabilized and two other major manoeuwres were performed to correct an eastward drift and increase the orbital height. On 16 July Apple reached its intended orbit, with its antenna pointing towards Nagpur in central India.

The experiments in telecommunications techniques began on 22 July, and the bulk of the programme should be completed in spite of the reduction in the satellite's useful life from two years to one and the 160 watts of power available instead of the planned 280 watts. After the earlier anxiety, scientists at Apple Mission Control Centre in Sriharikota are buoyant at having manoeuvred the spacecraft successfully.

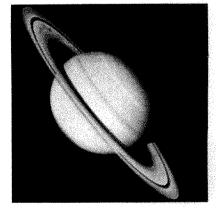

Good news was long overdue for the Indian space programme, for only 9 days after its launch aboard India's own SLV-3 launcher on 31 May, the remote sensing satellite Rohini II had burned up in the atmosphere — far short of its expected lifetime of 90 days. Rohini I was also ill-fated, crashing into the Bay of Bengal in August 1980 only a few days after launch.

Meanwhile, provided it is still functioning, Apple is to be used to broadcast nationwide an address from Prime Minister Indira Gandhi on Independence Day, 15 August. Only a few metropolitan centres will be able to pick up signals, but it marks a beginning to the plan to bring communications up to date throughout the Indian subcontinent.

Sunil Saraf

Saturn seen by Voyager 2 as the spacecraft approaches its encounter with the planet on 26 August, en route to Uranus (1986) and Neptune (1989). In the light of the results of the Voyager 1 encounter last November, the experimental programme of Voyager 2 has been considerably revised. Next week's *Nature* is a special Saturn issue containing new results from Voyager 1 and a description of the Voyager 2 mission by Dr Edward Stone, the Voyager mission's director.

The issue will also contain the usual features, including a report on the total synthesis of an interferon gene.

CORRESPONDENCE

Scientists in the Soviet Union

Sir — News of oppression crosses my desk daily. It is so commonplace that after a while its impact is almost lost. Like physicians who must become hardened to deal daily with death, human rights workers become somewhat inured to a daily fare of suffering. Nothing breaks down this shell more quickly than a visit to the victims of oppression.

As executive director of the Committee of Concerned Scientists. I went to the Soviet Union recently to investigate at first hand the trying circumstances confronting refusnik and dissident scientists. I found that the familiar litany of persecutions continues unabated. Most scientists who apply for emigration or speak out in defence of human rights are dismissed from their jobs. The regime then does its utmost to ensure their intellectual death by isolating them from their colleagues. In their personal lives too these individuals are plagued by countless harassments. Their homes are searched, their telephones disconnected, their mail intercepted. Scientists who apply to emigrate are routinely refused exit visas on spurious grounds. Anti-semitism is rife in all phases of academic life from admission to universities, to conferral of degrees, to obtaining employment. Those who have fallen from grace are frequently threatened with prosecution on criminal charges. Some are tried and sentenced to prison, labour camp and internal exile. These violations of human rights and scientific freedom are not new developments. Regrettably we have been hearing about them for some time.

I had learned much about this bleak situation during my four years with the Committee of Concerned Scientists. But I was not prepared for reports of the latest acts of persecution. Harassment has assumed new forms. Even prisoners are subjected to additional vengeful punishment. The health and very lives of prisoners of conscience Sergei Kovalev, Yuri Orlov and Anatoly Shcharansky are in grave jeopardy. Lengthy periods of solitary confinement, reduced rations and inadequate medical attention have taken their toll.

Other ominous trends in the treatment of refusniks and dissidents emerged from my discussions with leaders of these communities. First and most distressing is the wave of trials of scientists. Never before have so many activist scientists been threatened with lengthy sentences at one time. In Kiev Vladimir Kislik was sentenced to three years in a labour camp. Several years ago authorities had sought to imprison him for "compromising secrets" in an article published in an international journal. Yet this research had been officially cleared for publication some five years earlier. When confronted with a flood of protests from Kislik's Western colleagues pointing to the absurdity of this charge, the authorities backed off. In June, however, they achieved their goal through a contrived criminal charge. Computer scientist Viktor Brailovsky, a leader of the Moscow Sunday Scientific Seminar since its inception nine years ago, has been sentenced to five years of internal exile for advocating the right to emigrate, deemed defamatory to the Soviet state. In Leningrad,

refusnik mathematician Yevgeny Lein will also soon face trial. Interestingly, Kislik, Brailovsky and Lein all played key roles in organizing seminars designed to maintain the scientific skills of refusnik scientists.

The attempt by the Soviet authorities to close down these unofficial seminars is another cause for alarm. While seminars in provincial cities, such as Kiev and Vilnius, were squelched, those in Moscow and Leningrad had operated over a period of years with relatively little interference until recently. The Moscow Sunday Seminar, which had been blocked in the wake of Viktor Brailovsky's arrest in November, was able to resume regular Sunday sessions unmolested in early February. But this respite was short-lived; the authorities have shut it down three times since the end of April. On one Sunday during my visit at the end of May, the KGB barred the way to three different apartments making it impossible for a session to take place. Also in Moscow Alexander Lerner's seminar on mathematical biology, which recently held its 200th session, was blocked twice in April and May. In mid-May the seminars went into official recess for the summer. Our Soviet colleagues anxiously await the official reaction when they attempt to resume their

meetings in the fall.

Still another cause for concern is the use of academics as an instrument for persecution. Many scientists are now refused exit permits not because of allegations (usually unfounded) that they know state secrets, but simply because they are well educated. In fact the head of the administration department of the Communist Party's Central Committee bluntly told scientists that they are being detained "because you have degrees". At the same time the authorities are punishing scientists by abrogating their advanced degrees. Indeed three refusnik scientists told me their degrees had been revoked for "unpatriotic behaviour," that is, exercising their legal right in applying to emigrate.

While the situation of refusnik and dissident scientists has deteriorated alarmingly over the past year, this course is reversible. We can have an impact. Witness the return of Benjamin Levich, Mark Azbel, Valentin Turchin and others to productive scientific life due to the untiring efforts of Western scholars. We cannot afford to become hardened to the plight of oppressed colleagues who have much to contribute to a vital international science.

An Irish question

SIR - In your editorial of 25 June 1981 (p.601), you quite rightly in my view criticized the Science and Engineering Research Council (SERC) for turning down the proposal "that there should in future be an exchange of graduate students between the the United Kingdom and the Irish Republic on the modest scale of a dozen or so a year". You may not be aware that the Department of Education (N. Ireland) awards postgraduate studentships to good graduates who have normally been resident in N. Ireland for at least 3 years immediately preceding the start of the proposed period of study. One type of research studentship, the so-called XNI award, is tenable at institutions in Great Britain or the Republic of Ireland or exceptionally, outside the British Isles. This arrangement, which I believe has existed for many years, meets the points you make about student exchange in respect of graduates from N. Ireland. Unfortunately, there is no reciprocal arrangment in the Irish Republic.

I have had several enquiries from final-year honours students reading biochemistry in the Republic who would like to have carried out postgraduate research in this department. The only suggestion I have been able to make is that the prospective research students should apply to Queen's University for a Visiting Studentship of which there are about two per annum for the whole world including Great Britain. Competition is very keen for these studentships and the prospects of success are small. Perhaps you should give the Ministry of Education in the Irish Republic a nudge in addition to the black mark which you awarded to SERC.

University cuts

SiR — Union members have expressed particular concern over two aspects of the leading article "Change wanted" (*Nature* 11 June, p.442).

(1) It seems to accept the principle of cutting back on funding of universities, an extraordinary position for a journal concerned with science and research.

(2) It does not answer the questions and propositions posed by Swinnerton-Dyer but suggests the necessary financial savings can be made by college managements acting in a managerial capacity and shedding staffs from all sections except academic.

With regard to this last point, there is no suggestion as to how teaching laboratories and research groups could maintain their standards or volume of work when numbers of technicians and other ancillary staff, already at a bare minimum in many institutes, are reduced even further.

You cannot fail to be aware that the whole question of Swinnerton-Dyer is currently the subject of intense discussion not only in the university but also between the University of London and the trade unions that represent all sections of staff. We feel that these discussions should continue in a serious way on the basis of the evidence submitted in the discussion documents and that they should not be prejudiced by statements such as yours that the "armies of ancillary staff" should be chopped by the administrative action of the management of the schools.

NEWS AND VIEWS

The location of nucleosomes in chromatin: specific or statistical?

from Roger Kornberg

THE finding that histones are arrayed as nucleosomes along a DNA molecule immediately raised the question of whether the array occurs in a specific relationship, or 'phase', with respect to the DNA sequence1. Were this the case, then regulatory molecules might act in a novel way. For example, a protein responsible for setting a specific phase would determine which DNA sequences are protected by nucleosomes and which sequences are exposed in the regions between them. An alteration in this protein could shift the array of nucleosomes, exposing one set of sequences and covering up another. A single protein could thus control the function of a series of regulatory signals on DNA from a distance.

This intriguing possibility was investigated by comparing the distribution of nucleosomes on rat liver chromatin containing single-copy DNA with the distribution of nucleosomes formed essentially at random by reconstitution of DNA from the same source². The two distributions proved to be indistinguishable: no greater specificity with respect to sequence was apparent in the location of nucleosomes on the rat liver chromatin than in their location on the reconstituted chromatin. This ruled out a specific phase relationship of nucleosomes with rat liver DNA sequences.

An important assumption behind the notion of nucleosome phasing was that the spacing of nucleosomes was constant along a chromatin fibre and an array of nucleosomes thus periodic, akin to a linear crystal. If, however, there were no regular spacing, no long-range order, then a specific phase relationship between nucleosomes and DNA sequences could not persist for any distance along the DNA. This assumption was tested by two separate experiments which established that the spacing of nucleosomes is not constant, but variable within a cell^{2,3}.

Nonetheless, there have been several reports indicating that even if nucleosome spacing is irregular, it is not random; and

some indicating that it is both regular and non-random. Most of these experiments depend on the use of micrococcal nuclease, which cleaves DNA preferentially between nucleosomes, and they fall into three groups according to the extent of digestion. In studies of genes for heat-shock proteins and histones in Drosophila melanogaster4,5, very brief digestion of chromatin was followed by extraction of the DNA, cleavage with a restriction enzyme, gel electrophoresis and Southern hybridization with a restriction fragment produced by the same enzyme. This procedure reveals the length of DNA from the restriction site to the various points of cleavage in chromatin by micrococcal nuclease. Well defined locations of nucleosomes will result in a discrete set of DNA lengths and thus a pattern of bands, whereas random locations are expected to give a continuous distribution. Invariably a series of bands extending for thousands of base pairs was observed. The bands were irregularly spaced and those approximately 130-230 base pairs (bp) apart were attributed to defined locations of nucleosomes, although this attribution is a little problematic because the nucleosome core DNA is generally not less than 146 bp

In experiments with genes for tRNA in chicken embryos6, micrococcal nuclease digestion was more extensive, sufficient to generate a mixture of nucleosome monomers, dimers, trimers, and so on. The mixture was fractionated according to numbers of nucleosomes by sedimentation in a sucrose gradient, and the location of tRNA genes within individual oligomers determined by extraction of the DNA and cleavage with restriction enzymes, as well as by other procedures. Once again, the locations of nucleosomes with respect to DNA sequence were found to be nonrandom, though only for a distance of about five nucleosomes from the tRNA gene after which they became indistinct. In

Roger Kornberg is in the Department of Structural Biology at Stanford University.

this case, the defined locations were regularly spaced, with a periodicity the same as that found by micrococcal nuclease digestion of bulk chicken embryo chromatin.

In a third set of experiments, very extensive digestion of chromatin with micrococcal nuclease was used to degrade all the DNA to 146-bp core fragments, which were then mapped with respect to specific sequences. A unique location of nucleosomes in African green monkey satellite chromatin and a set of alternative locations of nucleosomes on genes for 5S rRNA in Xenopus laevis⁸ were found in this way.

Additional evidence of both random⁹⁻¹⁶ and non-random¹⁷⁻¹⁹ locations of nucleosomes has come from restriction enzyme digestion of chromatin and from other approaches. We are thus left with a serious conflict that needs to be resolved. One view, widely shared²⁰, is that 'phasing' of nucleosomes is a general phenomenon of considerable biological interest, despite any evidence to the contrary. An alternative view is that the two sets of apparently conflicting data may be reconciled, for example by the following simple picture.

Nucleosomes are deposited essentially at random on DNA, subject to two constraints. First, they are not formed on DNA associated with other proteins, for example sequence-specific regulatory molecules such as repressors and activators, but are restricted to the regions of DNA between such molecules. Second, nucleosomes occupy 166 bp of DNA²¹⁻²³ and they may not overlap one another. The average locations of nucleosomes subject to these constraints have been determined by computation24. It is only average properties that are of interest, because all experiments are done on millions of genomes. Remarkably, although nucleosomes are deposited at random, the computations show a distribution with a periodicity and degree of order similar to that revealed by micrococcal nuclease digestion of bulk chromatin. Furthermore, near the

boundary of a region of nucleosomes. specific locations are strongly favoured, with regular spacings identical to the periodicity of bulk chromatin and with probabilities that gradually diminish until there is less than a 10 per cent preference over neighbouring locations at a distance beyond about five nucleosomes from the boundary.

The simple statistical picture can account for the evidence for non-random locations of nucleosomes on chicken tRNA genes, provided that there is a sequencespecific protein or structure in the vicinity of these genes to form a boundary for a region of nucleosomes. The presence of regulatory proteins near the 5' end of the genes would satisfy this requirement. The similarity between the distribution of nucleosomes computed on statistical grounds and that found in the experiments on tRNA genes is striking. Both distributions show a regular spacing of nucleosomes identical to the periodicity of bulk chromatin, and both show defined locations over a range of about five nucleosomes but not far beyond. Whereas these two distributions appear so very alike, both differ markedly from that reported for heat-shock and histone genes in Drosophila, where a pattern of irregularly spaced bands extending for thousands of base pairs was produced by very brief digestion with micrococcal nuclease and interpreted in terms of specific locations of nucleosomes. This interpretation can be questioned on several grounds, the most serious of which concerns the preference of micrococcal nuclease for cleaving certain DNA sequences²⁵. It has recently been shown that striking patterns of bands are produced by digestion of naked DNA and furthermore, that the patterns resulting from digestion of naked DNA and chromatin are the same 16,26-29. This specificity of digestion poses the greatest problem when the period of digestion is very brief. It creates a need for additional evidence to support the assignment of a band pattern to an array of nucleosomes, such as the physical demonstration of nucleosomes by sedimentation in a sucrose

A further difficulty is that the interpretation in terms of an irregular spacing but well defined location of nucleosomes leads to a contradiction. Irregular spacing can only be explained by sequence-specific binding of histones to DNA. This implies that the location of nucleosomes is the same in all tissues of an organism since the DNA sequence remains the same. However, the spacing of nucleosomes has been shown^{30,31} to vary between different tissues, so the locations of the nucleosomes cannot remain constant but must vary as well.

Although the formation of nucleosomes is unlikely to be strongly sequence specific, neither is it likely to be completely independent of sequence, and the

assumption of random deposition of nucleosomes in the statistical picture can only be regarded as an approximation. Other proteins that associate with nucleic acids in a uniform way, such as the coat protein of tobacco mosaic virus, show some preference, perhaps by an order of magnitude or more, for binding to some sequences over others. It would be surprising if a similar preference were not shown by histones. Indeed, there is clear evidence for such sequence preference in the distribution of nucleosomes on polyoma DNA³², and the non-random locations of nucleosomes on satellite DNA and 5S rRNA genes mentioned above may be explained in this way (or by this effect combined with that of proteins bound at specific sites, which will be frequent in these DNA repeat regions).

Perhaps the most striking example of specificity in the location of nucleosomes so far discovered is the specific absence of nucleosomes from a region of about 400 bp encompassing the replication origin and

promoters of the SV40 chromosome. The DNA in this region appears naked, as judged from accessibility to restriction enzymes and electron microscopy³³⁻³⁷. The 'DNase I hypersensitive site' adjacent to the 5' end of many genes undergoing transcription^{4,38-40} may represent a similar region of naked DNA. The exclusion of nucleosomes from these regions is most simply explained by the sorts of constraint on the location of nucleosomes mentioned above. Thus the binding of non-histone proteins to any two sequences less than 166 bp apart will prevent the formation of a nucleosome on the entire region between them. T antigen is known to bind in the vicinity of the replication origin of SV40, and other regulatory proteins are doubtless bound near the 5' end of active genes as well.

In all the cases of non-random locations of nucleosomes discussed here, the key question concerning biological significance is the degree of preference over adjacent locations. All known regulatory proteins bind their cognate DNA sequences with affinity many orders of magnitude higher than unrelated DNA. The processes that would be regulated by mechanisms involving nucleosomes surely require at least as great precision. The degree of specificity that can arise in the statistical picture described above is at most an order of magnitude and so would seem unlikely to have any biological role. It remains to be determined whether any greater precision is achieved in other examples of nonrandom locations of nucleosomes. Unfortunately the methods in use are incapable of giving this information. The experiments are carried out, for the most part, using enzymes that cleave anywhere in the region between nucleosomes, and the data that result are mostly qualitative, in the form of bands in gels, which are visually striking even when intensity of only a factor of two separates them from the background.

The biological significance of specific locations of nucleosomes, if they are found, is apparent, but the advantages of a statistical distribution of nucleosomes. while not as obvious, are also great. A statistical distribution allows the packaging of DNA without regard to the length or the sequence involved. Were there genuine 'phasing' of nucleosomes, the loss or addition of a single base pair could have deleterious effects. A statistical distribution, on the other hand, would accommodate the extraordinary variations of genomes observed in nature.

Thus there is no convincing evidence for ordered arrays of nucleosomes in a fixed relation to the DNA sequence over a distance of many thousands of base pairs. Constraints on a random distribution of nucleosomes resulting from the presence of other proteins at specific DNA sites may impose some short-range order, but the degree of this order is unlikely to be sufficient for biological specificity.

Stripped for action

from Peter D. Chantler

STRIPPING proteins down in order to assess the individual functions of their peptide subunits has long been a preoccupation of biochemists. Hexameric myosin molecules are an ideal choice for this practice and an investigation of the role of the essential light chain in vertebrate skeletal muscle myosin was recently reported in *Nature* by Wagner and Giniger (Vol. 292, p.560).

All muscle myosin molecules contain two heavy chains (molecular weight ~ 2×105) and two pairs of low-molecularweight light chains (molecular weight ~ 2×10^4 each). One of these pairs comprises the DTNB light chains, so called because they were first partially dissociated from rabbit skeletal myosin using DTNB (5,5'-dithiobis [2-nitrobenzoic acid]). However, because their removal (in amounts greater than 1.5 moles per mole myosin) was found to have no effect on the $(Ca^{2+} + K^{+} - EDTA)$ - or actin-activated ATPase activities of myosin, they have also been described as 'non-essential'. In contrast, the other pair of light chains became known as 'essential' because their removal by various treatments always seemed to result in an irreversible loss of these ATPase activities; although as heavy chain denaturation appeared to precede essential light chain removal, the precise role of the essential light chain remained ambiguous.

The problem is further complicated in skeletal muscle by the presence of myosin isozymes. Thus there are two forms of essential light chain, A1 and A2; both exist within a single muscle cell¹ and the presence of myosin homodimers and heterodimers of A1 and A2 light chains has been confirmed²⁻⁴. In addition, at least two forms of heavy chain exist within fast skeletal myosin⁵.

Using the results of earlier workers as a guide, Wagner and Weeds⁶ found that in 4.7 M NH₄Cl, 2 mM EDTA and 2 mM dithiothreitol, pH 7.0, an equilibrium existed between dissociated essential light chain and heavy chain⁶. A 10-min incubation at 4°C did not adversely affect the ATPase activities. Exchange experiments were easily feasible in the presence of excess light chain, using isolated chymotryptic subfragments of myosin, S-1 (A1) and S-1 (A2), containing Al and A2 essential light chains respectively. These two types of myosin 'head' are easily separated on a DEAEcellulose column and lack the non-essential DTNB light chain, which is digested away by the chymotrypsin leaving the essential light chain intact. The results of such exchange experiments, now well known,

Peter D. Chantler is in the Department of Biology, Brandeis University, Massachusetts.

were that the kinetic parameters of the two subfragments appeared to be determined by the type of essential light chain, provided the assays were performed at low ionic strength (6mM)⁶; at higher ionic strength the parameters are virtually indistinguishable for the two isozymes⁷.

To study the separate roles of the heavy chain and essential light chain, Wagner and Giniger have now combined two powerful approaches: the above exchange procedure and the antibody column techniques of Holt and Lowey2, with the additional trick of including nucleotide in all these procedures to stabilize the nude heavychain fragment (so simple that one wonders why nucleotides were not included in dissociation experiments years ago). Thus, S-1 (A2) was incubated for 5 min at 4°C in 4.7 M NH₄C1, 5 mM ATP, 2 mM EDTA, 2 mM dithiothreitol, 0.1 M imidazole, pH 7.0, and then applied to an anti-essential light-chain antibody column equilibrated in the same buffer. The antibody is fully operational in these conditions and removes the dissociated A2 light chain. The subfragment eluting from the column still possesses about 10 per cent of A2 light chains but retains 50-100 per cent of the ATPase activities and 100 per cent of the actin-binding capabilities of S-1(A2) that has been similarly treated but not passed down the antibody column. Contaminating S-1 (A2) can be removed by second passage of the material through the antibody column in the absence of NH4 C1, to give a pure, active heavy-chain fragment. These results have been substantiated by Sivaramakrishnan and Burke (submitted for publication) who have used a different approach to produce light chain-free heavy chains of rabbit S1; the heavy chains retain full ATPase and actin-binding capabilities.

Taken together, these results show that the essential light chain is, in fact, inessential! They suggest that the active site and the actin-binding site are exclusive to the heavy chain in the head region of mvosin. The essential light chain (now a misnomer) can modulate this activity at low ionic strength but the activity is primarily determined by the heavy chain. The combined work of Wagner and Giniger and of Sivaramakrishnan and Burke represents the first clear demonstration of an active myosin heavy chain, free of light chains (notwithstanding the active minimyosin heavy chain from Acanthamoeba8 which is regarded as peculiar among myosins).

The corollary of pulling peptides apart is to reconstitute the original protein by adding together the constituents. Wagner and Giniger have not reported such an experiment, although it is possible and will be reported shortly by Sivaramakrishnan

100 years ago

PROF. Raoul Pictet of Geneva, who has been giving his attention of late to marine architecture, announces, according to the Times correspondent, a discovery which, if his anticipations be realised, will effect a revolution in the art of shipbuilding and greatly augment the speed of sea-going and other ships. The discovery consists in a new method of construction and such an arrangement of the keel as will diminish the resistance of the water to the lowest possible point. Vessels built in the fashion devised by Prof. Pictet, instead of sinking their prows in the water as their speed increases, will rise out of the water the faster they go, in such a way that the only parts exposed to the friction of the water will be the sides of the hull and the neighbourhood of the wheel. In other words, ships thus constructed, instead of pushing their way through the water, will glide over it. According to the professor's calculations, steamers built after his design will attain a speed of 50 to 60 kilometres the hour. A model steamer on the principle he has discovered is being constructed at Geneva From Nature 24, 18 August, 362, 1881.

and Burke. In a sense, however, the thunder of such a reconstitution experiment has been stolen by direct exchange experiments producing hybrid myosins9 using essential light chains of skeletal myosin and heavy chains of cardiac myosin, and vice versa. The results of these hybrid experiments indicate that the ATPase properties of myosin are largely determined by the heavy chain, in agreement with the results above on S-1.

Thus relatively minor roles have been assigned to the essential light chain and the DTNB light chain of skeletal myosin. Furthermore, the role of phosphorylation of the DTNB light chain in skeletal myosin remains an enigma. This is in contrast with the role of the regulatory light chain in scallop myosin (chemically related to the DTNB light chain), also deduced from stripping experiments, of governing

actomyosin interactions by determining the structure of the calcium-specific switch situated on the scallop myosin molecule 10,11. There is also increasing evidence for involvement of the essential light chain of scallop myosin in this regulatory mechanism 12,13. In addition, many recent papers point to the importance of regulatory light chain phosphorylation in smooth muscle and non-muscle myosins.

Is it possible then that the DTNB and

essential light chains of vertebrate skeletal myosin represent vestigial peptides — protein subunits whose principal role of regulation has long since been usurped by thin-filament control and the evolution of an architecture devoted entirely to efficient, repetitive contraction? In this context the increased stability conferred on the heavy chain by the presence of the essential light chain and the small modulation of actin binding by DTNB

light-chain phosphorylation¹⁴ may be seen as evolutionary vestiges of a once important regulatory role; the loss of the calcium-specific site could be seen as an example of 'silent' mutations. Whatever the merits of such a depressing (for some) speculation, it is clear that Wagner and Giniger, together with Sivaramakrishnan and Burke, have performed a long awaited and much needed experiment and thereby given us ample food for thought.

A glimpse of new results: the preliminary Solar Maximum Mission data

from Robert Rosner

THE first extensive reports of results from the (partially defunct) Solar Maximum Mission (SMM) satellite have recently appeared in the Astrophysical Journal Letters (244; L133, 1981). Following the precedent set by the Einstein Observatory consortium two years ago, the SMM experimental teams joined in submitting a series of papers which has now been published as a single issue of the Letters. Most teams contributed two papers: the first describing the particular experiment and its in-flight observational capabilities, and summarizing some of the principal preliminary results; the second focusing on a particular event or observation. The SMM observational programme also had a strong ground-based component, which is in evidence both in the accompanying article by Rust et al. 1 and in the individual papers (in which simultaneous radio and other ground-based data figure quite strongly in guiding the interpretations). The result is a useful overview of solar physics research conducted from SMM (as well as of the ancillary ground-based work), concentrating on the solar flare problem, and a good indicator of the quality of the data base generated by SMM. Astronomers wishing to acquaint themselves with the current status of the solar flare problem can do little better than to combine the reading of this volume of Astrophysical Journal Letters with a perusal of the Skylab Solar Flare monograph2. SMM will clearly provide significant observational constraints for flare theorists.

The SMM satellite carried on board seven instruments (see refs 3,4 and refs therein), six of which were spectroscopic, specifically optimized to observe dynamic events in the solar chromosphere and corona; the seventh instrument was a very broad-band (active cavity) radiometer intended primarily for temporal studies of the total solar irradiance. The energy range of the spectrometers spanned from the visible (6,583 Å) to 160 MeV, with the only significant gap in the extreme UV (in which, unfortunately, fall a number of

strong resonance lines from plasma species at transition region temperatures, such as O v_I [1,032 Å]). I will attempt here to describe what I believe are the main features of the results reported by the seven experimental teams.

Coronagraph/polarimeter (C/P). The C/P was a coronagraph capable of highspeed multicolour photometry and polarimetry. Built by the High Altitude Observatory (Boulder; L.L. House, Principal Investigator [PI]), it was specifically designed to observe transient coronal mass ejection with high time resolution and short response time (to flare onset alarms) as close to the solar limb as possible⁵. The instrument had a spatial resolution of 100 arc s and was capable of observations as close as $\sim 0.51 R_0$ from the solar limb; the spectral range covered was 4,435-6,583 Å, with particular emphasis in these reports on the classic coronal green line of Fe xiv (5,303 Å) and the red line of H α (6,563 Å). The preliminary data presented by Wagner et al.6 of the large coronal transient of 7 April 1980 are largely morphological, as the detailed calibration required to retrieve plasma diagnostic information had apparently not been completed. The images presented are, however, spectacular; successive images show rapid motions in both radial and nonradial directions, with peak velocities near 650 km s-1 at the outermost edges of the transient. Simultaneous radio observations made with the Culgoora three-frequency radioheliograph established the presence of a moving type IV source very near the outward-moving loop (surprisingly the 80-MHz source moved differently both in time and space from the 43-MHz source). Analysis of the radio data shows that the magnetic energy density in the transient region exceeded the thermal energy density, a conclusion which is essentially independent of the emission mechanism hypothesized as responsible for the observed radiation; and, if the instrument

Robert Rosner is at the Harvard-Smithsonian Center for Astrophysics.

calibration bears out the estimates for excess mass in the transient made by Wagner et al., one finds that in this event. the kinetic energy density is comparable with the magnetic energy density, and so far exceeds (by at least an order of magnitude) the internal (thermal) energy density. The conclusion - that estimates of total flare energies released based solely on the observed radiative fluxes can be mistaken by up to several orders of magnitude - is a caution well known from previous flare studies7. Furthermore, these observations confirm the conclusions of the Skylab Solar Flare workshop that loop transients must be driven largely by lorentzian forces, rather than by gaspressure gradients8.

Ultraviolet spectrometer and polarimeter (UVSP). The UVSP team (E. Tandberg-Hanssen, PI) comprised members of many collaborating institutions, including the Marshall and Goddard Space Flight Centers, the High Altitude Observatory (Boulder) and the Lockheed Palo Alto Research Laboratory. Spanning the spectral range 1,170-3,600 Å, the telescope/spectrograph laid claim to both the highest spatial $(3 \times 3 \text{ arc s})$ and spectral ($\lambda/\Delta\lambda \sim 150,000$) resolution on SMM; in addition, the instrument could carry out polarimetric observations, using a MgF, waveplate (and thus was, in principle, capable of the first measurements of the four Stokes parameters in the solar UV spectrum below 2,000 Å). One of the most surprising results of SMM in fact derives from the UVSP polarimetry: using observations of circular polarization of the 1,548 Å line of C Iv above a large sunspot, Tandberg-Hanssen et al.9 derive a line-of-sight magnetic field strength of $\sim 1,100\pm300$ G. This remarkably high field strength (considering the height of formation of the C IV line) is based on an assumed Doppler width, and so it is crucial that the measurement be confirmed in further detailed studies. If it were confirmed, standard models for the extrapolation of magnetic fields above sunspots might need

substantial revision. Another observational feature reported by Tandberg-Hanssen et al. is the detection of significant oscillatory mass motions above sunspots. Using the C_{IV} line once again, the UVSP found oscillations with periods of ~ 130 and ~ 170 s over two different spots; the fluctuations were in phase over four adjacent pixels (which were repeatedly rastered) but out of phase by ~ 180 deg in the blue and red sides of the line for any given pixel. It is not certain to what process such oscillatory motions are attributable, although calculations of the wave motions of flux tubes by H. Spruit (Max Planck Institute) and B. Roberts (St Andrews University) and collaborators appear very promising. Studies of the spatial and temporal behaviour of the density in the transition region of solar active regions, as determined from the intensity ratio of the Sizy (1,402.8 Å) and Ozy (1,401.2 Å) lines, show further evidence for a substantial level of dynamical behaviour in 'quiescent' regions. Thus, the UVSP has observed very large (~5-10 times) spatial variations in transition region densities on scales of ~ 4 arcs, as well as temporal variations on time scales of minutes or less. From the point of view of modelling, it is relevant to ask whether the observed fluctuations take place within magnetically 'confined' plasma structures (for example, whether they occur at the re-entrant footpoints of hot coronal 'loops'). If so, then these data suggest that the transition regions of coronal 'loops' are far more complex in their behaviour than allowed for in standard models for quiescent loop structures. Turning to yet more dynamic phenomena, Woodgate et al. 10 discuss thoroughly the morphological aspects of the limb flares of 30 April 1980, as seen in the C_{IV} line discussed above; several of the other teams have in fact found it useful to take advantage of the high spatial resolution imaging capability of the UVSP to place their (lower-resolution) observations in the proper geometric 'context'. The main conclusion of Woodgate et al. seems to be that, although the pre-flare state resembles the scenario of models for flare initiation of, for example, Canfield et al. 11 and Heyvaerts et al. 12 — a small loop of emerging flux rising into an overlying complex of magnetic loops — the detailed evolution of loop brightening and plasma motions does not. This conclusion must be tempered by the realization that it may not be reasonable to confront a theory which is designed to explain the 'primary' flare features with morphological details it may be, in principle, incapable of accounting for (see ref.2 for a particularly lucid account of this difficulty in flare research).

Soft X-ray polychromator (XRP). The XRP actually consisted of two instruments, the flat crystal spectrometer (FCS), with spatial resolution of 12×12 arc s and spectral resolution of $\sim 1,000$ at 20 Å, and the bent crystal spectrometer

(BCS), with a substantially lower spatial resolution of 6×6 arc min, but far higher spectral resolution ($\lambda/\Delta\lambda \sim 25.000$). The experimental team reflects a collaborative effort between Lockheed Palo Alto (L.W. Acton, PI), Mullard Space Sciences Laboratory (J.L. Culhane, PI) and the Rutherford and Appleton Laboratories (A.H. Gabriel, PI). One of the most interesting results reported of the SMM mission is the XRP observations of strong line broadening in both quiescent active regions and flaring regions. For example, Acton et al. 13 discuss the observations of quiescent active regions with the FCS; the spectra show substantial broadening beyond the thermal line width (which is estimated on the basis of electron temperatures inferred from the measured Ne IX/Mg XI line flux ratio). Assuming an isothermal model. Acton collaborators derive r.m.s. speeds of ~100±28 km s⁻¹ and argue convincingly that the excess broadening is probably due to random motions on spatial scales far smaller than the 'loop' structures themselves. How these observations relate to specific proposed coronal heating mechanisms is not yet clear because virtually all the current contenders predict some level of flow 'turbulence'. Turning to higher spectral resolution, a nice example of the power of spectroscopy is provided by the analysis of BCS flare data by Culhane et al. 14. These authors show in a succinct and convincing way that: (1) electron temperatures via the satellite-to-resonance line flux ratio for Ca $x_i x k$ and Fe $x_i x y j$ lines can be obtained, and the Fe lines are formed in different regions than the Ca lines (suggested by differences in derived temperatures, temperature evolution and intensity light curves; see also previous observations of the Caxix and Fexxvlines by Doschek et al. 15 and Feldman et al. 16); (2) line widths are strongly variable during the course of a flare, starting with rather broad profiles and narrowing significantly after the hard X-ray impulsive event; the broadening may be associated with turbulent flow speeds of $\sim 60-100 \text{ km s}^{-1}$; (3) fluorescence, rather than ionization by fast electrons, is the most plausible excitation mechanism for Fe Ka emission in at least some cases. In one case, however, the excellent temporal coincidence between a hard X-ray burst and an early Fe Ka 'spike' suggests (following calculations) that the energetic electrons responsible for the hard X-ray burst also excite the Ka transitions (in fact, calculation of the expected Ka flux from fluorescence yields far too little emission in this case).

Hard X-ray imaging spectrometer (HXIS). The HXIS was an imaging spectrometer with a field of view of 2 min $40 \text{ s} \times 2 \text{ min } 40 \text{ s}$ of arc at a resolution of $8 \times 8 \text{ arc s}$, and a field of view of 6 min 24 s $\times 6 \text{ min } 24 \text{ s}$ of arc at a resolution of $32 \times 32 \text{ arc s}$. It had some energy resolution covering the spectral range 3.5-30 keV in six channels and variable time resolution in

the range 0.5-7.0 s. The HXIS team (C. de Jager, PI) represents a collaboration between the Astronomical Institute at Utrecht and the University of Birmingham (UK). Its two contributions focused on providing a complete evolutionary description of the morphology and plasma characteristics of three flares observed in April 1980 (7 and 10 April: Hoyng et al. 17; 30 April: van Beek et al. 18). Although the gross morphological characteristics of flares seen in X rays were well established by the Skylab observations, these HXIS data illustrate the value of extending timeresolved imaging to higher photon energies. The flare observations in early April showed emission regions characterized by a hard spectrum to be spatially associated with, and to overlie, the brightest Ha emission patches, and furthermore that associated, softer emission components tended to lie between the harder components. If the emission source geometry is assumed to be that of a coronal 'loop', then a natural and immediate interpretation of these data is that the hard X rays are emitted at the loop footpoints (where the $H\alpha$ emission would be expected to take place), whereas the softer X rays are emitted at the top portion of a loop. If one views the footpoint excitation as a result of particle (electron) beams impinging on the dense footpoint boundary, then the 'thick target' model for the hard X-ray emission is clearly favoured. Further support for 'streaming' of fast electrons comes from the late-April flare data. Van Beek et al. show that the onset of flare emission could be associated with a very compact source and that the subsequent development of an extended 'tongue'-like component, whose temperature is higher than that of the compact component, is then consistent with production of energetic electrons within the compact component and subsequent streaming or diffusion into the larger (but magnetically confined) volume. In particular, this sequence of events is consistent with the time scale for the development of the extended source and the lack of clear evidence for large-scale mass motions within this source, and accounts well for the simultaneous appearance of an Ha 'tongue' spatially coincident with the extended X-ray tongue. Note that the above argument depends crucially on the assumed source geometry and that at X-ray wavelengths, SMM observers invoke the Skylab observations to justify their choice of loop geometry.

Hard X-ray burst spectrometer (HXRBS). The HXRBS (built by the Goddard Space Flight Center; K.J. Frost, PI) was not an imaging instrument and so provided no spatial resolution (the field of view encompassed the entire Sun). However, the lack of spatial resolution was compensated by high sensitivity and extremely high (1 ms) temporal resolution (because the probability of more than one flare occurring is low and because the

quiescent corona contributes a negligible fraction of the observed emission, source confusion for the HXRBS is of little concern); the spectrometer covered the ~25-400 keV energy range in 15 channels. The HXRBS team chose to discuss observations of three flares (29 March, 30 April and 7 June 1980) for which the timeresolved data allowed access to a previously inaccessible observational domain (Dennis et al. 19; Orwig et al. 20). The combination of large effective area with high potential time resolution allowed this instrument temporally to resolve several hard X-ray bursts into subfeatures: a combination of short (~1 s), quasi-periodic 'sub'-bursts, separated by 1-2s and characterized by a fairly hard spectrum, and a much softer, slowly varying component. In addition, HXRBS detected persistent intensity fluctuations significant down to the 100 ms level and spectral variability down to a time scale of seconds. By taking advantage of the capability for simultaneous observations with the other SMM (as well as ground-based) instruments. Orwig et al. were also able to compare the details of their light curves of the 30 April flare with those obtained with the UVSP, HXIS and BCS. The onset of Ca xix resonance line broadening discussed above seems to be well correlated in time with the onset of the impulsive burst and essentially all the flux observed by the HXRBS probably derives from a small loop (seen by the UVSP) coincident with one of HXIS's 8×8 arc s pixels.

y-Ray spectrometer (GRS). The short wavelength limit of solar radiative emission was explored by the GRS, an instrument whose experimental team (E.L. Chupp, PI) reflects a collaboration between the University of New Hampshire, the Max Planck Institute for Physics and Astrophysics (Munich) and the Naval Research Laboratory (Washington, DC). At these energies, the Sun emits both a continuum and a number of y-ray lines; the latter are thought to arise from the interaction of fast ions with the denser portions of the solar outer atmosphere. y-Ray emission is thus a direct diagnostic for the presence of, for example, accelerated ions and examination of the spectral and temporal behaviour of the emission provides a clue to the characteristic of the incident fast particles (compare with ref. 21, p.117). The GRS explored the energy range ~ 0.3-9 MeV with an energy resolution of ~7 per cent (FWHM at 662 keV) and a time resolution of ~ 16 s (or, using the 'burst window' 64 ms time resolution in the very limited singlechannel energy range 330±25 keV). The two contributions of the GRS team (Chupp et al. 22; Ryan et al. 23) focused on analysis of continuum and line emission from two flares; only in one were both the continuum and lines detected. Of particular interest are the data for the flare of 7 June 1980, for which the first detailed observations of the full light curve of the 2.223 MeV line from

the reaction $n+p\rightarrow^2H+y$ were obtained. The power of nuclear physics to 'recreate' the sequence of events which must have led to the emission of this y-ray line (as well as the continuum) is nicely laid out: not only must both electrons and nucleons have been accelerated, but the time constraint on neutron production (imposed by the requirement that the fast neutrons be thermalized before ¹H capture and the 2.223 MeV photon emission occur) is such that the fast ions responsible for their production must have been accelerated in virtual time coincidence with the fast electrons. This result imposes a non-trivial constraint on particle acceleration mechanisms anticipated (as an SMM result) at the time of the Skylab Solar Flare workshop (see ref. 21, p.162).

Active cavity radiometer irradiance monitor (ACRIM). ACRIM was the only SMM instrument not specifically designed for the study of flare transients. The culmination of an evolutionary sequence of successively more refined radiometers built by R.C. Willson (Jet Propulsion Laboratory), ACRIM was the first instrument put into orbit which had some assurance of resolving solar irradiance fluctuations to better than 0.1 per cent, and thus promised to aid in resolving the raging debate on the constancy of the solar irradiance. This promise has evidently been fulfilled. Two distinct questions arise: first, is there any evidence for variation in the solar constant (such as integrating the solar bolometric flux at some fixed radius over 4π steradians)? Second, is there any evidence for variability in the solar irradiance (such as in the total flux as seen from ~1 AU)? The second question (which is the only one a single spacecraft can sensibly answer) is intimately connected with a classic problem of solar physics: where does the radiative energy 'missing' from sunspots go? Several alternative solutions have been proposed, all constrained by the long known fact that there is (to some photometric precision) no evidence for a bright ring surrounding sunspots (compare with refs 24-26 and refs therein). These alternatives include redistribution of the missing energy over a sufficiently large portion of the solar surface, redistribution in spectral range (to the far UV or X rays), redistribution in transmission mode (conversion of radiative flux to magnetohydrodynamic waves), redistribution in time (storage in the convection zone, followed by gradual release over a substantial portion of the surface) and, most recently, spatial and angular redistribution (by means of the solar faculae 27). The first observational problem is of course to detect the effect of the passage of a sunspot across the solar disk on the total solar irradiance. This goal has been admirably met by ACRIM: Willson and Hudson28 demonstrate fluctuations of the total solar irradiance of the 0.05 per cent level; but a correlation with specific solar surface activity could not be established in this preliminary analysis. The vagaries of publication are such that even before the appearance of the 'SMM' Astrophysical Journal Letters, Willson and his collaborators published29 a more extensive analysis of their observations in Science; thus it is already well known that the 'dips' in total irradiance seen by ACRIM correlate well with the passage of sunspots across the solar disk (confirming previous Nimbus data suggesting, but not establishing, a similar correlation). The next task will be to identify definitively the source of the 'peaks' in total irradiance; it should then be possible to answer the 'missing flux' problem of sunspots.

The preliminary results discussed above suggest that, as the SMM data are more fully analysed and their implications for theoretical work better appreciated, SMM will contribute significantly to solar research, particularly in the areas of spatially and/or temporally resolved spectroscopy, imaging at hard X-ray photon energies and solar irradiance variability. It is to be expected that the interpretation of SMM data, which understandably received relatively less weight in these presentations of preliminary results, will play a far greater part in the next round of SMM presentations. It is noteworthy that the new Japanese satellite, ASTRO-A, is observing solar atmospheric dynamics with instruments very roughly comparable with the BCS and HXRBS. Given the premature failure of SMM's pointing capability, it is fortunate that it may, after all, be possible to follow up some of the discoveries revealed by the studies of the SMM data set.

Jupiter tail phenomena upstream from Saturn

F. L. Scarf*, W. S. Kurth†, D. A. Gurnett†, H. S. Bridge‡ & J. D. Sullivan‡

‡ Center for Space Research, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Voyager 2 plasma wave and plasma probe measurements from February 1981 suggest that phenomena associated with a well defined tail of Jupiter have been detected at a distance of about 6,200 $R_{\rm J}$. This indicates that Saturn's magnetosphere will be affected by the jovian tail and that by comparing Voyager 1 and 2 observations information on the physics of Saturn's magnetosphere can be obtained.

BEFORE Voyager arrived at Jupiter, the possibility of encounters with Jupiter's extended tail during the subsequent Jupiter-to-Saturn phase was noted¹. It was shown that in the spring and summer of 1981, Voyager 2 and Saturn would both cross the expected region of tail or wake about $7,000-8,000\ R_{\rm J}$ downstream from Jupiter and that this tail might cause a change in characteristics of Saturn's magnetosphere². In August 1980, Voyager investigators found evidence that Jupiter's tail extends out to at least $700\ R_{\rm J}$ (ref. 3). Here, we report Voyager 2 plasma wave measurements from February 1981 which are evidence for a well-defined distant tail of Jupiter at least 3 AU downstream, indicating that Saturn's magnetosphere will be affected by the jovian tail^{1,2,4}.

Tail encounter at $R = 6,200 R_1$

Jovian continuum radiation was detected by the Voyager 1 plasma wave instrument as soon as the spacecraft entered the dayside magnetosphere5, but the most intense signals were observed when Voyagers 1 and 2 were both traversing the nightside tail lobes⁶⁻⁸. Indeed, we regard the detection of this continuum radiation from the Voyager 16-channel spectrum analysers as the single plasma wave measurement characteristic most clearly associated with a spacecraft location within Jupiter's magnetosphere. Therefore, when Voyager 1 and 2 detected roughly similar plasma wave emissions after leaving the nominal close-in magnetosphere, simultaneous measurements from the on-board plasma probes were used to identify whether the spacecraft had re-entered Jupiter's magnetosphere. One Voyager 1 event (with $R = 163 R_{\rm J}$, $\phi = 245^{\circ}$) and six Voyager 2 events (with $184 R_J \le R \le 706 R_J$, and $\phi = 224-225^\circ$) were recognized as true encounters with the extended tail (here, ϕ is the azimuth angle in a right-handed Jupiter-centred system. with $\phi = 0$ oriented towards the Sun). The other 19 events, detected when the Voyagers were still in the solar wind, were interpreted in terms of leakage from an extended tail into a low-density solar wind trough, which would act as a wave guide, allowing signals from the distant tail to reach the spacecraft.

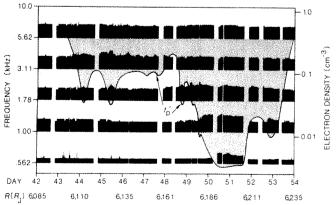

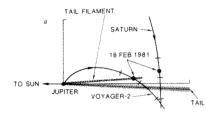

Fig. 1 Time profiles of average electric field strengths detected in five spectrum-analyser channels of the Voyager 2 plasma wave instrument. The scale on the right-hand side refers to the plasma density that gives an equivalent electron plasma frequency $(f_p^- = 9.000 \sqrt{N_e})$.

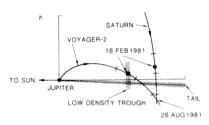

Fig. 2 Paths of Voyager 2 and Saturn with respect to the hypothetical extended tail of Jupiter (a Jupiter-centred Sun-oriented coordinate system is utilized). a, b, Different models that could account for the 18 February 1981 detection of continuum radiation from Jupiter's magnetosphere.

As Voyager 2 continued towards Saturn, the ϕ -value reached a maximum in summer 1980, and after that, the spacecraft moved progressively closer to $\phi = 175-180^{\circ}$, where the extended tail of Jupiter might again be encountered. One of the first very clear events indicative of an actual distant tail traversal occurred in mid-February 1981, and Fig. 1 shows the corresponding wave measurements for the interval 11-22 February 1981; the time profiles of the average electric field strengths detected in 5 of the 16 spectrum analyser channels are displayed. For each channel, the height of the black area is proportional to the logarithm of the electric field strength averaged over a 12.8-min interval, and the distance between the baselines for adjacent channels represents three orders of magnitude in amplitude. The scale on the right-hand side refers to the density that gives an equivalent electron plasma frequency $(f_p^- = 9,000)$ $\sqrt{N_e}$, where N_e is electrons cm⁻³ and f_p^- is in Hz).

Figure 1 shows that tracking was almost continuous during this 12-day interval and that there were several small but abrupt level changes from one relatively steady amplitude to another. The upper eight channels (1-56 kHz) are mildly affected by a failure in the flight data system^{3,8}, leading to small repetitive or quasi-periodic sequences of changes in background (see, for example, the 1-kHz data for days 43-45). Figure 1 also shows natural (or irregular) changes in levels for the channels from 562 Hz to 5.62 kHz, and the line f_p traces the lower envelope of these variations. We interpret this as detection of continuum radiation from Jupiter's extended tail, and we need to determine whether Voyager 2 was within the tail or connected to it by a solar wind density trough.

These two possibilities are shown in Fig. 2, which uses a Jupiter-centred Sun-oriented coordinate system to show the paths of Voyager 2 and Saturn with respect to the hypothetical

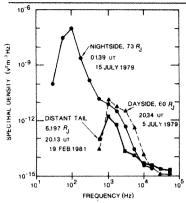

Fig. 3 Spectral densities of continuum radiation detected on Voyager 2 in 1979 (near Jupiter) and 1981 at 6,200 R. Lowfrequency cutoff varies as the local plasma density changes, but the striking similarities in the spectra at high frequencies suggest Voyager 2 was back in Jupiter's tail early in 1981.

extended tail of Jupiter. Bars on the Voyager and Saturn curves represent the positions on 1 December 1980, 1 April 1981 and 1 August 1981 (more trajectory information is given in ref. 1), and the locations for 18 February 1981 are marked with dots. In mid-February, Voyager 2 was still well above the nominal $\phi \simeq 177.5^{\circ}$ position for an aberrated anti-solar tail configuration, but had the tail fragmented as indicated in Fig. 2a, it is quite likely that Voyager 2 would have been within a tail filament at this time and could have been 'connected' to the tail by a low-density trough as indicated in Fig. 2b.

Voyager 2 plasma probe measurements suggest both phenomena were operative. For the early interval, days 43-48, the spacecraft was apparently immersed in streaming plasma which could have been low-density solar wind, or even a wake region around a tail filament; the same applies for the end of the interval (days 52, 53). However, for the period centred around 19 February (day 50) when the $f_{\rm p}^-$ -profile of Fig. 1 was drawn between f = 300 and 500 Hz, the Voyager 2 plasma probe detected no streaming ions, and we propose that at this time the spacecraft was back in Jupiter's tail. Besides the filament hypothesis it is possible that a solar wind disturbance displaced the main tail3.

During the 3-day period which includes this apparent crossing of the distant tail, Fig. 1 indicates that $f_{\rm p}$ (min) was ~400 Hz, leading to $N_e(\min) \approx 2 \times 10^{-3}$ electrons cm⁻³. This N-value yields a current higher than the plasma probe threshold for ion measurements in the streaming solar wind, but if the flux is lowered because the flow speed is also much reduced, then no plasma will be measured. Thus, the absence of detectable plasma during this period, when N_e was at a minimum is consistent with an actual entrance into the tail cavity.

A final test of the tail-crossing hypothesis involves searching the plasma wave noise spectrum for the characteristics associated with continuum radiation. Figure 3 contrasts characteristic close-in continuum radiation spectra for 5 and 15 July 1979, with a distant tail spectrum from 19 February 1981; for $f \ge 1$ kHz all three spectra have very similar shapes, but at low frequencies there are marked differences. The complete 1979 Jupiter measurements indicate that the continuum radiation has an essentially constant spectral shape throughout the magnetosphere⁶⁻⁸, and that the observed changes are primarily associated with variations in local plasma density, leading to shifts in the low-frequency cutoff. Thus, we associate the 5 July 1979 cutoff at $f \approx 1$ kHz with a local electron density of about $0.01 \,\mathrm{cm}^{-3}$, and the $f \approx 50 \,\mathrm{Hz}$ cutoff on 15 July 1979 with an extremely low local density value near 3×10^{-5} electrons cm⁻³ Because for $f \ge 1.0$ kHz, the continuum noise spectrum detected at $6,200 R_1$ has essentially the same shape as the spectrum measured on 15 July 1979, when Voyager 2 was at 73 $R_{\rm J}$ on its way to the initial exit from the magnetosphere, this strongly supports the concept that Voyager 2 was again in the magnetosphere. Indeed, Fig. 3 shows that the high-frequency tail spectra from 15 July 1979 and 19 February 1981 differ no more from each other than the two close-in noise spectra. These comparisons suggest that Voyager 2 was within Jupiter's tail on 19 February 1981, and that the tail confines the noise extremely well, or that the continuum radiation is generated within the distant tail.

The demonstration³ that many of the earlier tail-associated events involved leakage of continuum radiation into low-density solar wind troughs argues against an explanation based on noise confinement over a distance of $6,200 R_1 \approx 3 \text{ AU}$; thus mechanisms that produce continuum radiation far from Jupiter seem more promising. One such process involves production of electromagnetic waves by mode conversion from electrostatic upper hybrid resonance emissions. Observations related to the terrestrial plasmapause, the Io torus boundary, and the perturbations of Saturn's plasma disk at the positions of Tethys, Dione and Rhea¹⁰, suggest that strong mode coupling and intense electromagnetic radiation generally originate in regions with steep plasma density and temperature gradients.

That the magnetopause boundary also has steep gradients in plasma density and temperature suggests that continuum radiation could be generated all along the boundary. The initial Voyager 2 report⁶ clearly showed that intense upper hybrid resonance emissions and weaker continuum radiation were detected immediately after the spacecraft crossed the dayside magnetopause at $71.5 R_{\rm J}$ on 5 July 1979. Thus, we speculate that trapped continuum radiation at Jupiter is generated in the region of the magnetopause, so that its appearance at $6,200 R_J$ does not require strict confinement of the waves. This explanation can also readily account for the similarity in the noise spectra, as Barbosa¹¹ has proposed a wave-scattering mechanism with the spectrum of the continuum radiation controlled by fluctuations of the magnetopause surface.

Discussion

The filament picture in Fig. 2a is consistent with many aspects of the 1981 Voyager 2 measurements but it is useful to consider other sources of information. We can learn much about the possible configurations of extended magnetic tails in the solar wind by studying the structures of comet tails, as far downstream from any interplanetary object the only significant characteristic of the source region involves the close-in size of the obstacle. For visible comets in the inner Solar System, there is no firm knowledge of the true obstacle size, but the theoretical model of Biermann et al. 22 gives a contact surface or obstacle radius, $R_{\rm B}$, of $\sim 10^5$ km. As the subsolar Jupiter magnetopause is nominally located at $R_B \approx 56 R_J$, this means that the 18 February 1981 measurements were taken at $R \approx 110 R_B$. For the comet case, 110 R_B translates to a downstream distance of about 1.1× 10⁷ km, and many photographs of the visible ion tails of fresh comets show clear evidence of filaments extending to this distance or beyond (for instance, comet Kohoutek, Fig. 1 in ref. 13). This fact suggests that filaments may develop naturally in extended magnetic tails and that Voyager 2 will continue to encounter them.

If the extended tail of Jupiter has this type of structure, then Saturn itself is likely to have many brief encounters with the jovian tail cavity leading to significant differences between the Voyager 1 and 2 Saturn encounters. It will be of great interest to search Voyager 2 data for such effects, including variations in magnetosphere size, bow shock location, radio emission strength and trapped radiation belt population.

Stratospheric aerosols properties from Earth limb photography

M. Ackerman, C. Lippens & C. Muller

Belgian Institute for Space Aeronomy, Circular Avenue, 3, B-1180-Brussels, Belgium

Balloon-borne observation at three wavelengths of visible sunlight scattered by the Earth limb allows the determination of aerosols abundances and size distributions at various altitudes in the stratosphere. The stratospheric aerosols are apparently still under the influence of the Mount St Helens volcanic eruption five months after its occurrence on 18 May 1980.

IT is only relatively recently that detailed studies of the stratospheric aerosols have been initiated. They are of importance because nucleating and catalytic agents are central in determining the radiation balance of the atmosphere. A survey of light scattering techniques used in the remote monitoring of atmospheric aerosols has been published recently. Twilight phenomena have been used both from the ground^{2,3} and from satellites, and Earth-limb observation from space has been based on sunlight scattering observed directly^{4,5} or through its absorption⁶. In situ sampling initiated 20 years ago⁷ has also provided much information on the composition of aerosols⁸.

We have previously reported the photographic observation, from a balloon gondola floating in the upper stratosphere, of the enhancement of stratospheric aerosols over Europe 23 days after the Mount St Helens volcanic eruption. Several other reports have now appeared 10-13 while details have been provided on the air trajectories which have caused the volcanic plume to move at various altitudes in various directions¹⁴ at the beginning of their many cumbersome revolutions around the Earth. Much information has been collected on the properties of the ejecta in relation to atmospheric effects¹⁵. On 15 October 1980, five months after the eruption, another photographic balloon flight took place. One of the first observations was finding that the enhancement of stratospheric aerosols below 20 km altitude has become very horizontally homogeneous. This means that it is now possible to determine the basic properties of volcanically influenced aerosols and of natural aerosols which seem to differ in several respects in the stratosphere.

Observation method

Photographic cameras onboard a balloon gondola simultaneously record at various wavelengths the light from the Earth limb below the horizontal line-of-sight while the solar elevation is low. This light is scattered direct sunlight with a contribution from the Earth albedo which is minimized when the Sun is low. The observation geometry is shown in Fig. 1. The limb radiance, R, can be expressed directly in solar radiance units because solar images are recorded simultaneously with a known attenuation factor. The solar elevation is calculated from the time that the picture was taken and from the geographical position. An angular scale is constructed from several consecutive shots. The depression angles at which radiances are measured are related to the line-of-sight altitude of closest approach to the Earth surface taking into account refraction effects¹⁶. The measured integrated radiances can be inverted taking into account absorption by ozone and air along the line of sight by the 'onion pealing' method to yield the in situ radiance, R^* , per unit length versus altitude.

The Sun-oriented gondola can be rotated about its vertical axis so that pictures can be taken at various azimuth angles, A, relative to the Sun's position. The scattering angle θ of direct

solar radiation can be computed from the relationship

$$\cos \theta = -\sin D \sin h_{\odot} + \cos D \cos h_{\odot} \cos A \tag{1}$$

where D is the depression angle at which the atmospheric radiance is measured and h_{\odot} is the solar elevation angle at the time of measurement. As expected from their strong forward scattering properties, aerosols re-emit little light at an azimuth angle 180° away from the direction of the Sun. The limb radiance observed in this case is used to subtract Rayleigh scattering and to isolate aerosols scattering at all azimuths taking into account the Rayleigh phase function 17 .

If direct solar radiation only is considered, an *in situ* monodisperse aerosol radiance R_a^* per cm of pathlength is related to the average solar radiance R_{\odot} by

$$R_a^* = R_{\odot} \pi \alpha^2 Q_s \sigma \varphi_{\theta} n / 4\pi \tag{2}$$

where α is the angular radius of the Sun's disk, 2.16×10^{-5} rad, φ the properly normalized particulate phase function, Q_s the scattering efficiency factor, σ the particulate scattering geometrical cross-section in cm² if the number density, n, of the particles is expressed in cm⁻³.

In practice, our data confirm the previous observation¹⁸ according to which the phase function can, within experimental uncertainties, be represented by the Henyey-Greenstein function. The asymmetry factor g of the phase function and the total scattering efficiency can then be determined. The variation

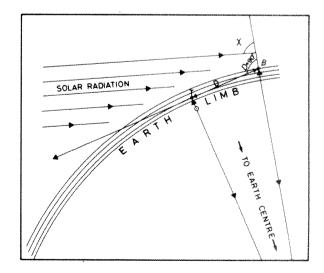

Fig. 1 Observational geometry: quasi parallel light falls on the atmosphere at a solar zenith angle χ , the atmosphere is seen at various depression angles D; through the rotation of the gondola, photographs are taken at various azimuth angles A from the Sun direction.

of these parameters with wavelength can be fitted to their theoretical variations using the effective size parameter of Hansen and Travis¹⁹. This procedure, which uses the Mie scattering computation programme of Wiscombe²⁰, leads to an evaluation of the effective particle size and provides information on other properties. From these two quantities and from the product $n\sigma$ obtained directly from equation (2) the value of n can be deduced.

The aerosol particle size is usually treated in terms of the wavelength, λ , of the interacting light through the Mie size parameter

$$x = 2\pi a/\lambda \tag{3}$$

where a is the radius of the spherical particle in a monodisperse aerosol. In a polydisperse aerosol the number of particles of radius r is expressed 19 by

$$n_r = Ar^{(1-3b)/b} e^{-r/ab} (4$$

where a becomes the effective radius while b is a measure of the width of the size distribution; A is a constant related to the total number of particles.

Comparing R_a^* with θ , the scattering angle, at various wavelengths provides information about the asymmetry factor, g. A knowledge of g and its variation with the wavelength of the interacting light leads to the unique determination of a and b. How the scattering efficiency Q_s varies with size parameter can then be determined. The behaviour of these quantities is known from the Mie scattering theory.

Experimental details

The balloon flight took place on 15 October 1980, the tropopause height being 11.4 km. The gondola floated at 37.6 km altitude and was equipped with seven Hasselblad EL 500 cameras with 80-mm focal length lenses and 70-mm films. Four of them were pointing forwards, one being loaded with colour EPR 475 Kodak film, and three in the opposite direction. The

six black and white cameras contained (each camera was paired with the one opposite): Wratten filters 47 (440 nm) and 25 (650 nm) with Plus X Kodak film and filters 87 with Kodak aerographic 2424 film (860 nm). To ensure that the Sun images were in the dynamic range of the film, neutral density screens made of exposed and processed sheet films were placed 60 cm from the lenses with their lower edge placed a few centimetres above the optical axis. Before flight, step wedges, inconel filters and samples of the neutral density screens illuminated in parallel light were recorded by each camera in the laboratory. After the flight, the Plus X films were processed using the Kodak D76 developer ($\gamma = 1$) and the IR-sensitive film was processed in the Kodak D19 developer ($\gamma = 2.3$). The dynamic range of this last film was too small to record usefully simultaneous Sun and limb images so that its absolute calibration was derived from the comparison of optical densities due to quasi-pure Rayleigh scattering observed 180° from the Sun in the three colours above 30 km altitude. The absolute calibration in blue and red light was based directly on solar images. The colour, blue, red and IR camera settings (aperture, speed) were respectively: f/11, 1/125 s; f/8, 1/250 s; f/8, 1/250 s; f/8, 1/125 s. As soon as the gondola could be Sun oriented, pictures were taken during ascent and later during the float period. With its Sun sensor remaining locked on the Sun, the gondola was then rotated about its vertical axis so that the cameras could record Earth limb images 65°, 115°, 180°, 245° and 295° from the solar azimuth. The whole horizon scan took place between 16.08 and 16.18 h GMT, during which atmospheric illumination conditions changed very little. The latitude and longitude were respectively 1° E and 44° N. The average solar azimuth and elevation angles were 248° and 9.3° respectively. The optical densities were measured on three tracks per frame normally to the horizon by means of a Jarrell-Ash micro-densitometer and subsequently converted into radiance, in units of solar radiance, versus altitude of the grazing line of sight every 200 m. Each photograph allows an horizontal angular coverage of about 34°.

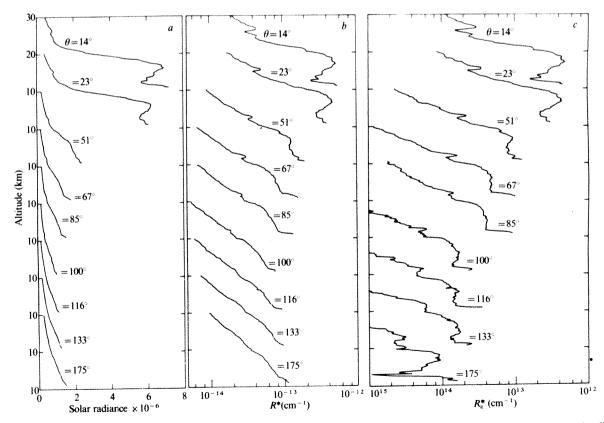

Fig. 2 Data at 650 nm versus altitude for various scattering angles, θ : a, integrated radiances, R, along the lines of sight; b, inverted radiances, R^* ; c, inverted radiances due to aerosols, R^* . Each successive lower curve is displaced by 10 km altitude from the one above. R^* and R^* are expressed in units of solar radiance.

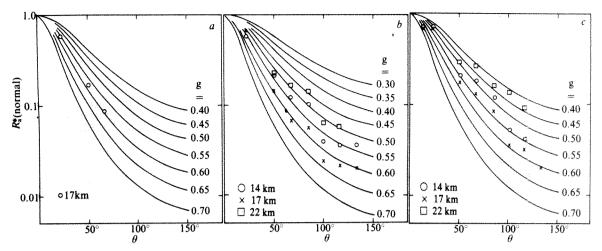

Fig. 3 Henyey-Greenstein phase functions of the radiance versus scattering angles, normalized at $\theta = 0^{\circ}$ for various values of the asymmetry factor, g. The experimental data points are shown at the three altitudes studied and for the three wavelengths: a, 440 nm; b, 650 nm; c, 860 nm.

Results

As an example, the observed limb radiance values are presented versus the altitude of closest approach of the line of sight to the Earth surface (sea level) for 650 nm and for various scattering angles in Fig. 2a.

The comparison of the vertical radiance profiles observed at small scattering angles in red light 11 days before, less than 1 month⁹ and five months after the Mount St Helen's eruption shows several characteristics. A radiance enhancement peaking at 17 km altitude still exists on 15 October 1980, by a factor of almost three relative to the pre-eruption value. Above 22 km altitude the radiance has returned to values close to what it was on 7 May 1980. This suggests that the heavy layer observed over England on 6 and 7 June¹⁰ and on 5 June⁹ over France constituted the main body of the material injected in the stratosphere by the volcano. Over 5 months, that layer would then have spread in altitude and its centre of gravity would have moved upwards by ~2 km, this being perhaps related to air heating through sunlight absorption by the aerosols.

The various photographs taken around the vertical axis of the gondola reveal the 17 km layer at all azimuth angles; above 20 km altitude a well defined 1-km thick layer is readily seen. Such thin, well separated features have been observed on each of our previous flights and most probably have no relationship with volcanic activity. They belong to the 'natural' stratospheric aerosol. In this particular case the layer is present towards the south from the gondola and absent towards the north. Its altitude is at 22 km from 125° azimuth counted clockwise from the geographical north to ~220° where it begins to rise up to ~25 km at 250° where it splits and becomes invisible. Particulate matter is also present above, what we call here, the 22 km layer. With respect to the horizontal homogeneity, the comparison of the aerosol direct sunlight scattering with the scattering angles is safe for the 17-km layer; for higher altitudes care must be taken.

For the angular study, along the lines-of-sight integrated radiances are inverted using standard ozone and air distributions²¹ and their respective absorption cross-sections^{17,22}. The *in-situ* radiance values, R^* , in units of solar radiance and per cm along the line-of-sight at the tangent altitude, are presented in Fig. 2b. The R^* values at 650 nm (Fig. 2b) show at $\theta = 175^{\circ}$ an exponential dependence versus altitude, as expected, on which some structure and noise is superimposed. At 860 nm in the backward hemisphere where aerosols are expected to bring a small contribution and particularly at 30 km altitude, the variation of R^* with θ fits well the Rayleigh phase function, giving confidence to the very low contribution from the Earth albedo to the observed signal. This is not surprising as the average cloud deck radiance measured at depression angles from 5 to 15° ranges from 7×10^{-7} to 6×10^{-7} of the solar

radiance at respective azimuths from 0 to 180° from the Sun. At $\theta = 14^{\circ}$ and 17 km altitude the aerosol contribution is about 14 times the Rayleigh contribution.

At 650 nm (Fig. 2b) the Rayleigh phase function can be fitted to the radiance variation observed in the backward hemisphere at 30 km altitude. In this case, however, the average cloud radiance varies from 6×10^{-6} near the Sun's azimuth to 6×10^{-7} elsewhere. In the forward direction the aerosol contribution to the radiance is 10.8 times the Rayleigh contribution at 17 km. At 440 nm, Rayleigh scattering dominates even if at $\theta=14^\circ$ it still seems to be five times smaller than aerosol scattering at 17 km. At $\theta=175^\circ$, R^* grows faster than exponentially at altitudes below 20 km. Multiple scattering here has an important role because the Rayleigh optical thickness on the tangent line of sight reaches unity at 20 km. This occurs at 9 km and at ground level for 650 and 860 nm respectively. In addition the average cloud deck radiance is very high in blue light varying from 1.6×10^{-5} near the Sun to 10^{-6} of the solar radiance elsewhere. The data obtained in blue light can then only be used

Table 1 Summary of balloon-borne results for three characteristic altitudes

Altitude	14 km	17 km	22 km

with caution and at small scattering angle. The situation here is different from that in the balloon-borne aureole observation²³ due to the low solar elevation used.

Figure 2c presents the *in situ* radiance due to aerosols R_a^* obtained by subtracting the Rayleigh scattering R_M^* , due to air. R_M^* is evaluated from R^* at $\theta = 175^\circ$ following the 'clean air' procedure currently used in lidar work²⁴. R_M^* is then adapted for the various scattering angles considered according to the molecular phase function¹⁷.

Interpretation

The angular dependance of R_a^* has been fitted to the variation of the scattered light intensity with θ computed for various values of the asymmetry factor g of the Henyey-Greenstein function as shown for three wavelengths in Fig. 3. In blue light a few values of θ give useful results. For the reasons discussed above values for the 22-km layer have only been considered for θ between 51° and 116°.

The asymmetry factors so determined are listed in Table 1 with the optical scattering extinction coefficients $Q_s n\sigma$. The values at 440 nm have not been used because a model taking into account the measured cloud radiances indicates a nonnegligible contribution of the albedo to the limb radiance. But this contribution is negligible at the larger wavelengths. The observed g values, taking into account that it is probably slightly higher than 0.6 and 440 nm, tend to indicate that a value of the real index of refraction equal to 1.55 (see ref. 25) is observed here. This value will then be used to deduce the size parameter x, and its variation with λ from 650 to 860 nm leads to the values of a and b characterizing the size distribution listed in Table 1. Eventually, the scattering efficiency Q_s can be deduced from a and b following the Mie scattering theory¹⁹.

With the data available, there is, of course, another method of determining $\sum Q_* n\sigma$. From the air σ values¹⁷ and from the air number density $n_{\rm air}$ taken from a model²¹ (mid-latitude, spring-autumn) $(n\sigma)_{\rm air}$ can be evaluated. The $R_{\rm M}^{\rm M}$ values determined at $\theta=175^{\circ}$ by the 'clean air' method²⁴ are compared with the $R_{\rm a}^{\rm M}$ measured and by taking into account the air and aerosols phase

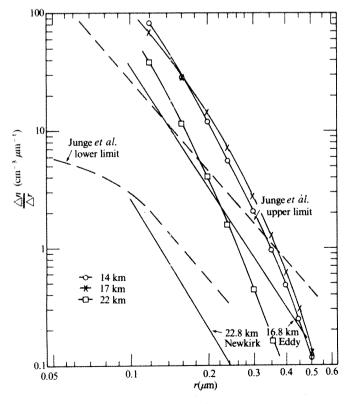

Fig. 4 Number of particles per cm⁻³ versus their radii and per micrometre size interval for three characteristic altitudes: 14, 17 and 22 km. Two previous data sets^{7,23} are shown for comparison.

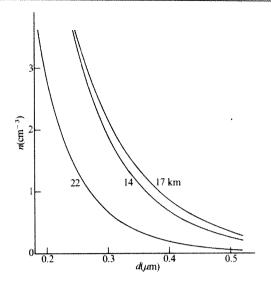

Fig. 5 Total numbers of particles with diameters larger than given values. The ratio of the number of particles with diameters $(d) > 0.3 \,\mu \text{m}$ to the number of particles with diameters $> 0.5 \,\mu \text{m}$ is larger for the layer at 22 km altitude than for 17 and 14 km altitudes indicating the volcanic influence in these two latter cases²⁹.

functions the values of $(\sum Q_s n\sigma)_{AM}$ for the aerosols are deduced. They are also listed in Table 1.

The absolute particle distribution shown in Fig. 4 for the three altitudes considered is based only on the geometrical extinction coefficient $\sum n\sigma$ at 860 nm for two reasons. In IR light, the albedo contribution to the measurement is negligible while it is a maximum in blue light and in the inversion of R leading to R^* the correction for the absorption by O_3 , of which a standard vertical distribution had to be used, is the largest in red light. This is supported by the discrepancy observed at shorter wavelength between the extinctions determined from the observed radiances and those determined by comparison with the molecular scattering. The agreement is very good at 860 nm. The Mie scattering theory also had the best chance to be valid, even if the particles do not exhibit a perfectly spherical and smooth shape, at small values of the size parameter.

Discussion

Our particle distributions are compared in Fig. 4 with the upper and lower limits deduced from in situ sampling and with two extreme values resulting from solar aureole measurements and the present results fall within the range of those data except for particles $< 0.2 \mu m$ radius where the upper limit given by Junge et al. sexceeded. As mentioned above the aerosols below 20 km are still in volcanically perturbed conditions. On the other hand, the collection efficiency of an in situ sampler might be reduced for small particles. Note also that our distributions are steeper especially at large radii. This effect is less pronounced in the comparison with the aureole data. This effect seems to be due to the small values of effective radii obtained here.

Another comparison of our data, shown in Fig. 5, can be made for the total number of particles with a radius $>0.15~\mu m$ obtained by balloon-borne optical particle counters²⁶. The number densities of these particles are 0.4-1.3 particle cm⁻³ in the 14-17 km altitude region and 0.1-0.9 particle cm⁻³ at 22 km. The data presented here for 22 km correspond to a low aerosol content above 20 km and lead to 0.7 particle cm⁻³ above $0.15~\mu m$. At 14 and 17 km altitude the values presented in Fig. 5 respectively imply 1.9 and 2.1 particle cm⁻³ of particles with radii $>0.15~\mu m$. A comparison between the two methods would be required to define a possible discrepancy as the aerosols are volcanically enhanced in the present case.

The optical extinction coefficient $Q_s n\sigma$ measured at 1 μ m wavelength by the SAM II satellite-borne instrument at low

aerosol load in July 197927 exhibits an almost constant value at altitudes from 14 to 20 km of 10^{-9} cm⁻¹. This compares very favourably with our 860 nm value at 22 km. At 17 and 14 km altitude, the extinction in the present case is 3 and 2 times larger. This can be expected from the volcanic influence which may also explain the larger effective particle radius a at 17 km altitude.

A value of the asymmetry factor g of 0.49 ± 0.7 has been measured recently at 633 nm, a wavelength close 650 nm used here, from 10.7 to 12.8 km altitude in the stratosphere 18. This value corresponds to our measurement at 22 km where the aerosol is considered to be purely 'natural'. Because g is larger in the present case at 14 and particularly at 17 km, one of the volcanic influences must then be to increase the g value and if the Mie theory is applicable to increase the particle size as we observe it at 17 km altitude.

From an optical point of view the particle size distribution, of which the shape is of greater interest than the particle concentration for radiative transfer calculations25, is variable in the stratosphere. The asymmetry factor, g, is smaller than the constant value (0.7) currently used in models.

For photochemical models of stratospheric aerosols²⁸ the variable size distribution will have a part to play. The molecular content of the condensed phase thought to be oxidized sulphur, water vapour and perhaps other species is not negligable for the gas phase either as conversion into vapour would lead to volume concentrations in the 10⁸-10⁹ molecules cm⁻³ at altitudes from 15 to 20 km.

Our measurements therefore confirm recent data and provide new information on critical points which are of fundamental importance in the evaluation of the role that stratospheric aerosols in the size range from 0.04 to 0.4 µm radius can play.

Extrachromosomal circular copies of the eukaryotic transposable element copia in cultured Drosophila cells

Andrew J. Flavell & David Ish-Horowicz

Imperial Cancer Research Fund, Mill Hill Laboratories, Burtonhole Lane, London NW7 1AD, UK

Circular copies of the transposable element copia have been isolated from cultured Drosophila cells. These molecules, which are present at approximately 1 copy per 10-50 cells, comprise a heterogeneous family of related species. Most are composed of a complete copy of the internal section of copia combined with either one or two copies of the flanking direct repeat sequences. Such structures are strikingly analogous to the circular proviral forms of retroviruses.

TRANSPOSABLE genetic elements were first defined genetically in maize1 and have since been found in a wide variety of organisms including bacteria^{2.3}, yeast³ and *Drosophila*³⁻⁵. They are capable of causing a wide range of genetic effects such as abnormally high mutation and reversion rates and chromosomal deletions or rearrangements. Recent experiments indicate that most, if not all, of these effects are connected with the ability of these elements to transpose to different sites in their host cell genomes. Although there is no direct evidence for analogous species in vertebrates, several observations strongly suggest that eukaryotic transposable elements and the integrated proviral forms of some retroviruses are related.

The following properties are shared by all eukaryotic transposable elements and integrated provirus retroviruses⁶⁻¹

• Their sequences are each composed of an internal DNA segment several thousand nucleotide pairs long flanked by a pair of identical DNA segments of several hundred base pairs (bp) which are both arranged in the same direct orientation on the element⁶⁻¹⁴ (Fig. 1). These repeat sequences are each bounded by small inverted repeats several nucleotide pairs long⁷

- The complete element is flanked by an identical pair of host DNA sequences, usually 4-6 bp long, that are present only once in the target site for integration^{7,10-12,14}.
- There is no detectable homology between the DNA sequences at the insertion site and the ends of the element.
- The terminal dinucleotides of a transposable element or integrated retrovirus provirus are 5'TG...CA3' and in some cases this sequence homology extends further into the elements,

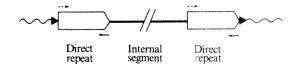

Fig. 1 Generalized structure of a eukaryotic transposable element or integrated retrovirus provirus. An internal segment of several kilobases is bounded by a pair of identical directly repeated sequences. These repeats carry small terminal inverted repeats several base pairs long which are normally imperfect (→ and ←). The complete element is flanked by an identical pair of host DNA sequences (>). The flanking genomic DNA is indicated (m).

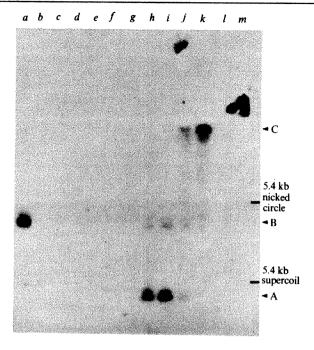

Fig. 2 Isolation of extrachromosc mal copia-specific DNA. Circular DNA was extracted from Drosophila cultured cells (Eschalier's Kc line²⁸; 1.5 × 10° cells) by a modificiation of the method of Hirt^{17,29}. The enriched sample was then subjected to CsCl-ethidium bromide ultracentrifugation. Nucleic acids were recovered from the fractionated gradient, dissolved in 10 mM Tris-HCl (pH 7.5) and 1 mM EDTA and treated with boiled RNase A (10 μg ml⁻¹ at 37°C for 15 min). 30% of each fraction was assayed for copia-specific sequences by agarose gel electrophoresis in 90 mM Tris-OH, 90 mM boric acid and 9 mM EDTA at 1.5 V cm⁻¹ 16 h, transfer to a nitrocellulose filter²⁰ and probing with ³²P-labelled nick-translated copia DNA³⁰ (a 5.1-kb Mspl fragment of the genomic clone cDm2056¹⁴ containing the entire copia element plus approximately 150 bp of flanking material). Dextran sulphate (9%) was used during hybridizatior³¹. The filter was exposed to Fuji Rx film with an intensifying screen at -70°C for 16 h. Lane a, 50 pg of the linear 5.1-kb copia Mspl fragment run in parallel, lanes b-m, gradient fractions 1-12 (fraction 1 is the bottom). The mobilities of supercoiled and nicked circular forms of the marker 5.4-kb plasmid pJB8 (ref. 29) are shown. Class A-C molecules indicate copia species which are described in the text.

for instance the *Drosophila* element *copia* shares with an avian retrovirus the sequence 5'TGT...TACAACA3' (refs 7, 13).

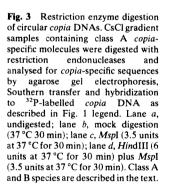

Although such shared properties are very unlikely to be coincidental, the exact relationship between transposable elements and integrated retrovirus proviruses is unclear. To probe further the similarities between eukaryotic transposable elements and retrovirus proviruses, we have searched for transposable element-encoded structures which are analogous to intermediates in the retroviral life cycle. One such intermediate is the circular double-stranded DNA copy of the viral RNA that is synthesized by the viral reverse transcriptase and is presumed to integrate into the host cell genome. The present report describes the isolation and characterization of closed circular DNA copies of the *Drosophila* transposable element copia whose structures closely resemble the circular forms of retrovirus proviruses. This observation further demonstrates the remarkable similarity between these classes of element.

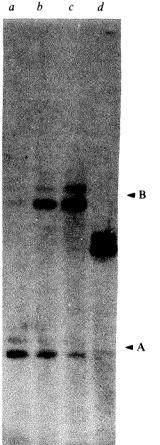

Isolation of circular copia DNA molecules

Extrachromosomal circular DNA was first described in *Drosophila* by Stanfield and Helinski¹⁵. *Drosophila* eggs and cultured cells contain a heterogeneous population of circular species with sizes varying from a few hundred nucleotides to 20 kilobases (kb). More than 80% of this DNA is homologous to middle repetitive DNA¹⁶ (sequences repeated ~100 times in the *Drosophila* haploid genome) of which the *copia* element is an example. It therefore seemed plausible that *copia* might be represented in *Drosophila* circular DNA.

Circular DNA was isolated from *Drosophila* culture cells by a modification of the method of Hirt¹⁷. The partially purified circles were separated from contaminating genomic DNA by CsCl-ethidium bromide isopycnic ultracentrifugation and the fractions from the gradient were assayed for *copia* sequences by agarose gel electrophoresis and Southern filter hybridization¹⁸. Three major size classes of *copia*-specific sequence were observed (Fig. 2): a fast migrating class (class A) which is shown below to comprise circular supercoiled molecules, minor amounts of nicked circular molecules with intermediate mobility (class B) and a slowly migrating class with a lower buoyant density containing high molecular weight genomic linear DNA (class C). The following experiments proved the assignments for class A and class B molecules; class C molecules were not studied further.

First, class A co-purifies with supercoiled mitochondrial DNA on the CsCl-ethidium bromide gradient (data not shown), strongly suggesting that class A is also supercoiled. Further evidence was provided by digestion of class A and class B molecules with restriction endonucleases. Gradient fractions containing the fast migrating class A copia species were pooled and digested with restriction enzymes which cut genomic copia elements once (HindIII) or not at all (MspI; Fig. 3). Mock digestion with no added enzyme led to partial conversion of class A (which in Fig. 2 is resolved into a doublet) into the more slowly migrating class B. DNA preparations of this purity usually contain low levels of contaminating nuclease which nick supercoiled circles to yield open circles. Thus, in the conditions of mock digestion, supercoiled class A circles were converted

partially into nicked class B circles. Digestion with MspI gave a similar result but addition of HindIII to this enzyme converted both classes of species into a doublet of slightly greater mobility than class B, presumably corresponding to linear molecules. We conclude that classes A and B in Fig. 2 are composed of supercoiled and nicked copia circles, respectively. Furthermore,

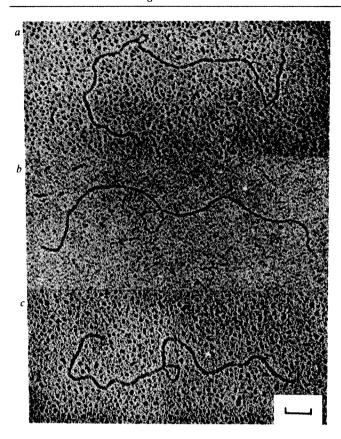

Fig. 4 Plasmids containing 5.0-kb (pBBl and pBB5), 4.7-kb (pBB3) and 4.2-kb (pBB6) inserts were digested with *Hin*dIII and *Msp*I restriction endonucleases to yield the linear insert DNAs (*Msp*I cuts the plasmid pAT153 to yield fragments smaller than 700 bp). Heteroduplexes between pair-combinations of these inserts were prepared and mounted ³². a, 5.0-kb and 4.7-kb inserts; b, 5.0-kb and 4.2-kb inserts; c, 4.7-kb and 4.2-kb inserts.

The bar indicates 0.1 µm.

there are at least two different sizes of circle, the smaller predominating.

The approximate yield of circular copia DNA recovered on the CsCl gradient was determined by comparison with known quantities of cloned copia DNA (Fig. 2). The hybridization signal from the circular copia DNA corresponds to about 50 pg of DNA from 4×10^8 cells, which is equivalent to 1 complete copia molecule per 50 Drosophila cells, assuming complete recovery. The actual recovery of circular DNA is difficult to establish but is likely to be ~25% (the value obtained from similar experiments by Smith and Vinograd)¹⁹, suggesting that the cultured cells studied contain 1 circular copia molecule per 10-50 cells.

Structure of cloned copia molecules

To analyse circular copia molecules more conveniently, these species were cloned into a bacteriophage λ vector. The circles were linearized by digestion with HindIII and then ligated into HindIII-cleaved λ Charon 21A. Approximately 1,000 copia-specific recombinant phage were detected; 13 of these were plaque-purified and phage DNA preparations were made. The size of the copia-specific DNA insert was determined in each of these purified phage by HindIII digestion followed by agarose gel electrophoresis. Two major size classes of insert were observed, 4.7 and 5.0 kb long. These two species are presumably derived from the two major size classes of copia circle visible in Fig. 2. Two examples of each of the size classes of recombinant, together with one phage containing a smaller 4.2-kb insert, were subcloned into plasmid pAT153²⁰ to simplify further analysis of the DNA.

To determine the relationship between these cloned DNAs, heteroduplexes between all three size classes of insert were visualized by electron microscopy (Fig. 4). Deletion loops were only observed between plasmids of different sizes, suggesting that the two members of each size class possess substantially similar sequences. Only single deletion loops were observed between plasmids containing inserts of different sizes, and the sizes of the loops correspond in all cases to the size difference between each pair of inserts. It therefore seemed likely that the 4.7-kb insert was a simple deletion variant of the 5-kb species and that the 4.2-kb species had a larger deletion in the same region.

Restriction mapping of the five plasmids (Fig. 5) confirmed this conclusion. All three classes of insert have similar restriction maps, the only difference between them being in the region between the unique PstI and PvuII sites. The 5.0-kb inserts have the restriction map predicted for an excised genomic copia element which has been circularized and cloned. In particular, these inserts contain the 280-bp BalI fragment predicted from the head-to-tail fusion of two direct repeats. The 4.7-kb inserts lack this BalI fragment and presumably contain only one direct repeat. The 4.2-kb insert has lost both the BalI fragment and a further 500 bp to the left of it.

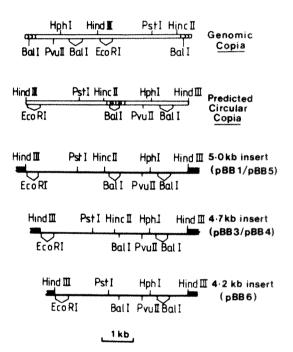

Fig. 5 Restriction maps of cloned copia circular DNA molecules. DNA of the vector phage & Charon 21A (a gift of R. A. Flavell) was treated with restriction endonuclease HindIII (Boehringer; fourfold overdigestion) and calf intestinal phosphatase (Boehringer, $0.02\ U$ per μg DNA for 30 min at 37 °C). The enzymes were inactivated at 70 °C for 60 min. Enriched circular DNA from Drosophila cultured cells (see Fig. 1 legend) was digested with HindIII and MspI restriction endonucleases, extracted with phenol and precipitated with ethanol. The cleaved vector DNA (2 µg) and insert DNA (~0.01 μg) were ligated in 0.01 ml 50 mM Tris-HCl pH 7.5, 10 mM dithiothreitol, 5 mM MgCl₂ and 1 mM ATP with T₄ DNA ligase (a gift from A. Udvardy) at 4 °C for 16 h. The mix was packaged into phage coats³³ and phage were plated on Escherichia coli K802 cells. Duplicate nitrocellulose filters were blotted from the plates³⁴ and hybridized to ³²P-labelled copia DNA as for Southern filters. Thirteen plaques showing hybridization were picked and the phage plaque-purified three times. Quick DNA preparations were made from suspension stocks of the phage³⁵. Insert DNAs from these phages were sized by agarose gel electrophoresis of *HindIII* digests. Eight phage contained 4.7-kb inserts, three contained 5.0-kb inserts, one contained a mixture of these two and one contained a 4.2-kb insert. Two examples of both the 4.7-kb and 5.0-kb inserts, together with the 4.2-kb insert, were subcloned into HindIII-digested pAT15320 and the resultant recombinants were used to transform HB101 cells to ampicillin resistance. Quick plasmid DNA preparations and large-scale preparations were by the method of Ish-Horowicz and Burke²⁹. A restriction map of a genomic copia element. (G. Rubin, unpublished) is shown and the location of the direct repeats (cm) is indicated. The predicted restriction map of a copia element, which has been perfectly excised from the recombinant plasmid cDm 2056¹⁴, cyclized and then cleaved at the unique HindIII site, is shown. Double cutting sites for Ball and EcoRI enzymes are indicated ()

Thus, the two major size classes of cloned circular copia DNA molecule seem to comprise intact copia elements circularized at the extreme ends of the element with or without the deletion of one direct repeat sequence. This result is very similar to that observed in cloned circular retroviral proviruses which also possess either one or two direct repeat sequences (usually termed long terminal repeats^{21,22}). The latter configuration is labile in bacteriophage vectors, with loss of one direct repeat sequence sometimes occurring by recombination during propagation²³. To prove that the cloned *copia* species containing one direct repeat were not derived from such artefacts, a sample of uncloned total Drosophila circular DNA was digested with three restriction enzymes (HindIII, HincII and PvuII) that easily distinguish between these two species. The copia-specific products of these digestions were identified by Southern filter hybridization. Fragments derived from molecules containing one direct repeat (0.9 kb) and two direct repeats (1.2 kb) in HincII/PvuII double digests of uncloned copia circles were observed (Fig. 6, lanes c, e), showing that both types of molecule exist in Drosophila cultured cells.

Restriction fragments characteristic of 4.2-kb circles were not detected in digests of uncloned circular DNA. This suggests that

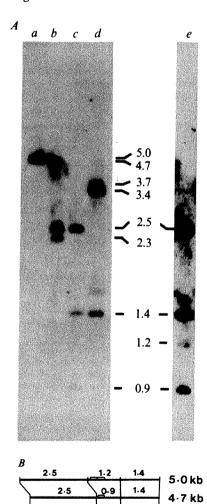

Fig. 6 Detection of circular copia molecules containing either one or two direct repeats in cultured cells. Samples of uncloned circular DNA from cultured cells were digested with restriction endonucleases and analysed for copia-specific sequences. A, lane a, HindIII plus MspI; lane b, HindIII plus MspI and HincII; lane c, HindIII plus MspI, HincII and PvuII; lane d, HindIII plus MspI and PvuII. Lane e is a longer exposure of lane c to reveal the 1.2-kb fragment characteristic of 5.0-kb circles. The sizes of copia-specific fragments were derived from comparison with parallel marker DNA fragments. B, the restriction maps of 5.0-kb and 4.7-kb insert DNAs for the enzymes used in these digests are shown. MspI does not digest either the uncloned or cloned copia DNAs but aids complete digestion in preparations containing uncloned copia circles for reasons that are unclear. The location of the direct repeats is indicated (

).

either these elements are derived from a cloning artefact or they constitute a small minority of the circular *copia* species. We favour the latter interpretation because deletions associated with prokaryotic transposons^{2,3} and in circular retrovirus proviruses^{24,25} have often been observed previously.

Origin of circular copia elements

Circular copia elements might be derived in several ways. First, they may be self-replicating plasmids. We think that this is unlikely because of their low abundance. Second, they may be synthesized by reverse transcription of copia RNA. Such RNA could be derived either from infecting 'copia retroviruses' or possibly from the full-length intracellular copia RNA which is abundant in cultured Drosophila cells⁶. These hypotheses are supported by evidence of reverse transcriptase activity and the reported presence of retrovirus-like particles in Drosophila cells²⁶. However, we favour a third interpretation, that they are derived from the relatively infrequent excision of genomic copia elements.

Excision of genomic copia by homologous recombination between the terminal direct repeats would generate the observed 4.7-kb circles possessing one direct repeat. Such excision would leave single copies of the direct repeats behind in the Drosophila chromosomes. These single copies were not detected in embryonic cells¹³ but cultured cells, which possess approximately fourfold more copias per haploid genome, were not probed for such sequences. We therefore cannot exclude the possibility that the 4.7-kb molecules are derived from such a mechanism. Homologous recombination between direct repeats could not yield 5.0-kb molecules containing two repeat sequences, although recombination between the flanking host 5-bp repeats (Fig. 1) would create such species. However, if such a mechanism is implicated, there must be greater control of excision because any given pair of 5-bp sequences occurs about once in every 1,000 bp in the Drosophila genome. If the excision of 5.0-kb molecules is based on homologous recombination, one copy of the variable flanking 5-bp repeats might be present between the fused direct repeats in 5.0-kb circles. Alternatively, if the 5.0-kb circles are derived by reverse transcription, it is likely that all these molecules possess an invariant sequence at the junction between the two direct repeat sequences. The sequence of cloned 5.0-kb molecules in this region is now being determined to test these predictions.

Eukaryotic transposable elements and retroviruses

The experiments described here indicate that eukaryotic transposable elements and retrovirus proviruses share close structural similarities. The isolation of circular *copia* elements whose structures are closely analogous to circular proviruses extends these common properties. Such similarities could be a result of either a common ancestry or convergent evolution. Temin²⁷ has pointed out, however, that convergent evolution would be unlikely to produce such close structural similarities and such a high degree of sequence homology at the ends of these elements. It therefore seems likely that these sequences are evolutionarily related.

The degree of relationship between present day transposable elements and retrovirus proviruses is difficult to estimate. If these species are closely related it is possible that retroviruses can transpose without using RNA intermediates; there is no evidence to support or discredit this hypothesis. It is similarly possible that all eukaryotic transposable elements are retroviruses, although this seems highly unlikely in the case of yeast transposable elements. Furthermore, the presence of transposons in prokaryotes suggests that transposable genetic elements are more widespread than retroviruses and probably predate them evolutionarily.

We therefore favour the hypothesis that a broad spectrum of related species exists in eukaryotes between the transposable elements of yeast and the non-defective retroviruses of higher

vertebrates which usually, if not always, transpose via RNA intermediates. All these species may, however, still share common intermediates, such as circular DNAs, and all may use similar cellular enzymes in their integration. We are now investigating whether copia circles can integrate into the Drosophila chromosomes to create normal genomic copia elements. Of course, if circular copia molecules are derived by

Transformation of rat cells by an altered polyoma virus genome expressing only the middle-T protein

R. Treisman, U. Novak, J. Favaloro & R. Kamen

Transcription Laboratory, Imperial Cancer Research Fund Laboratories, London WC2A 3PX, UK

A modified polyoma virus genome has been constructed which can encode the middle-T protein, but not the large-T or small-T proteins. This was achieved, starting with the full length viral DNA inserted into a plasmid vector, by replacing a small genomic restriction fragment spanning the middle-T intervening sequence with the equivalent fragment from a cloned partial cDNA copy of the middle-T protein mRNA. Transfection of the modified viral DNA into cultured rat cells efficiently induced the formation of transformed cell foci which gave rise to cell lines that grew as tumours after injection into Fisher rats. The only viral early-region antigen synthesized by the cell lines was the middle-T protein. Expression of the middle-Tprotein is therefore sufficient to establish and maintain a transformed state. The viral mRNA produced by two of the transformed cell lines was structurally indistinguishable from the normal middle-T mRNA found in productively infected cells, suggesting that RNA splicing is not an essential step in the biogenesis of this messenger.

THE early region of polyoma virus DNA encodes at least three polypeptides, the large-T, middle-T and small-T proteins (refs 1-4; reviewed in ref. 5). Conclusive evaluation of the individual roles of these proteins in virally induced oncogenic transformation has been difficult because the DNA sequences^{6,7} which encode them overlap extensively (Fig. 1). It is known that expression of the large-T protein is insufficient to transform cells 5,9, and that the 3'-terminal half of the early region, which encodes only C-terminal sequences of large-T protein, is not required to maintain 10,111 or to establish 12-15 the transformed state. Attention has therefore focused on the 5'-terminal half of the early region, which encodes the small-T and middle-T proteins as well as the N-terminal portion of the large-T protein. As all previously reported mutations within this region of the genome affect at least two of the three T-proteins^{9,16-19}, rigorous assignment of the resulting phenotype to a change in any individual gene product has not been possible. We now report the construction of an altered polyoma virus early region which encodes exclusively the middle-T protein, and describe the mode and consequences of the expression of this DNA when it is introduced into cultured rat cells.

Construction of a viral early region encoding only middle-T protein

We constructed a modified viral early region encoding exclusively the middle-T protein by specific deletion of the middle-T protein intervening sequence (see Figs 1 and 2). We achieved this, starting with a recombinant plasmid containing full-length wild-type viral DNA (p53.A6.6), by replacing a small genomic restriction fragment spanning the small-T and middle-T protein intervening sequences with the corresponding shorter fragment from a cloned partial cDNA copy²⁰ of the middle-T protein mRNA (Fig. 2). From the structures of the Py early-region mRNAs (ref. 20; Fig. 1) we predicted that the plasmid produced, pPyMT1, would encode only middle-T protein. The polyoma virus early-region mRNAs are generated by the differential splicing of a common precursor. This involves the ligation of two splice donors (at nucleotides 409 and 746) to two splice acceptors (at nucleotides 795 and 809) in three of the four possible combinations (Fig. 1). The mature mRNA for middle-T protein (spliced from 746 to 809) lacks the acceptor (at 795) used in large-T and small-T mRNAs. Moreover, as the highly

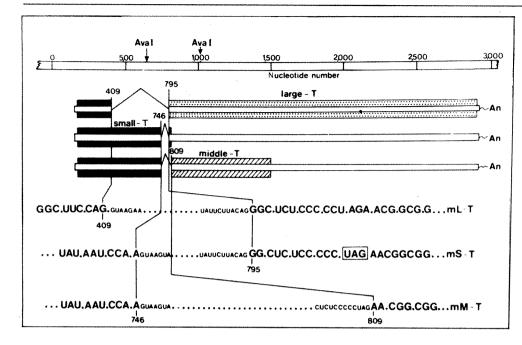

Fig. 1 The spliced structures of the principal Py early-region mRNAs. At the top of the figure is a linearized map of the Py early region, with conventional nucleotide numbers⁷ indicated. The three differentially spliced principal mRNAs²⁰ are aligned with this map. The coding regions of the mRNAs are boxed; solid boxes, dotted boxes and hatched boxes refer to reading frames (as defined in ref. 7) 1, 2 and 3 respectively. The nucleotide sequences across the splice joints²⁰ are shown in the bottom half of the figure.

conserved consensus sequences at splice donor sites lie largely within the intervening sequences 21.22, the splice donor at nucleotide 746 in the middle-T mRNA should also be inactive. The only potential splicing signal remaining in this mRNA would be the donor (at nucleotide 409) used in the large-T mRNA splice. The primary transcript of the viral early region in pPyMT1 (compare with sequence in Fig. 1) could therefore not be spliced to generate mRNAs encoding normal large- or small-T proteins, but it would encode the middle-T protein. A novel splice could perhaps join the large-T mRNA donor to an otherwise unused acceptor, but we considered this possibility to be improbable, and indeed such splices did not occur.

Transformation of rat cells with pPyMT1

We tested the biological activity of the viral genome in pPyMT1 by transfecting Fisher rat cells (F2408 cell line)²³, using the calcium phosphate technique²⁴, and quantifying dense foci overgrowing the normal monolayer which appeared after 2–3 weeks of incubation in the presence of 5% fetal calf serum (FCS). We used as a control the plasmid p53.A6.6, the parent of pPyMT1, which contains a normal polyoma virus genome (Fig. 2). In repeated assays, the transformation efficiency of pPyMT1 was 20–45% that of the control plasmid when non-saturating amounts of DNA were used (Table 1). No foci appeared when cells were transfected with carrier DNA alone, or with the plasmid vector and carrier DNA. Twenty foci induced by pPyMT1 and six induced by p53.A6.6 were picked and grown into cell lines for further analysis.

All the transformed cell lines were initially screened for the presence of viral T-antigens by indirect immunofluorescence using a serum from a Py tumour-bearing rat. Of the six control cell lines transformed by the unmodified parental plasmid, five showed the strong nuclear fluorescence pattern characteristic of the polyoma virus large-T antigen. None of the 20 cell lines derived from pPyMT1 transfections displayed such fluorescence, although many showed a weak specific immunofluorescence which appeared to be distributed throughout the cell.

Properties of rat cell lines transformed by pPyMT1

Eight pPyMT1 and two control lines were selected at random for more detailed study. The properties measured (Table 2) were saturation density, ability to form foci when grown with untransformed rat cells, ability to grow in semi-solid medium and morphology at low- and high-cell densities (Fig. 3). All 10 cell lines displayed, by these criteria, the usual range of phenotypes characteristic of polyoma virus-transformed rat cells. Those transformed by pPyMT1 could not be distinguished from the control cell lines. We conclude that from all of the parameters tested that the lines derived from pPyMT1-induced foci are transformed. We do not know whether differences between these cell lines and those transformed by genomic viral DNA might be demonstrable by measurement of other parameters of the transformed state. In particular, we have noted that many, but not all, of the pPyMT1-transformants grew poorly on plastic when seeded at very low cell densities in 5% FCS. We have also measured the ability of four pPyMT1-transformed (1.6, 1.7, 2.4 and 2.8) and two control (4.1 and 4.6)

Table 1 Transformation of F2408 rat fibroblasts by pPyMT1 DNA and control plasmid DNA

Expt no.	Plasmid	Amount (μg)	No. of foci	Foci per µg viral DNA	Ratio pPyMT1/ p53.A6.6

^{*} Transformed cells $(5\times10^2 \text{ and } 5\times10^3)$ were plated in separate experiments with either 2×10^5 (first number) or 2×10^4 (second number) F2408 rat cells on 50-mm dishes. Foci were counted after 14 days of growth in Dulbecco's minimal essential medium (DMEM) containing 5% FCS.

† Transformed cells $(5\times10^2 \text{ and } 5\times10^3)$ were grown in DMEM, 5% FCS, 0.3%

cell lines to grow as tumours after injection into Fisher rats. Tumours were produced within 3 weeks of subcutaneous injection of 4×10^5 cells in all six cases; lines 1.6 and 2.4 produced tumours when only 4×10^4 cells were injected.

Viral proteins synthesized by pPyMT1transformed cell lines

The prediction that the viral early region in plasmid pPyMT1 would encode only the middle-T protein was confirmed by analysis of the viral proteins synthesized by the transformed cell lines. A randomly selected set of cloned cell lines transformed by p53.A6.6 or pPyMT1 were labelled with 35S-methionine and the proteins precipitable by polyoma virus anti-T serum were fractionated on SDS-polyacrylamide gels (Fig. 4). In eight of nine pPyMT1 cell lines tested, the only specifically immunoprecipitated protein detected co-migrated with the normal viral middle-T protein synthesized in mouse or rat cells infected with polyoma virus. One line, 2.9, additionally produced a smaller polypeptide which is probably a truncated middle-T protein. The amount of middle-T protein produced was within the usual range obtained with Py-transformed rat cells. No large-T, truncated large-T, or small-T proteins were found. These conclusions were strengthened by analysis of the viral mRNA present in the cell lines, as discussed below. Two control lines transformed by the control plasmid p53.A6.6 were similarly analysed. Both synthesized middle-T and small-T proteins. One (4.1) also produced a full-length large-T polypeptide, while the other (line 4.6, which was T-antigen negative by immunofluorescence) synthesized a shorter polypeptide which was probably a truncated large-T molecule, like those frequently found in other polyoma virus-transformed rat cell lines 10,11

Viral mRNAs synthesized by pPyMT1transformed cell lines

We investigated the structure of the viral mRNAs in several transformed lines for two reasons: first, to demonstrate unambiguously that the pPyMT1 transcripts were not spliced to produce mRNAs which could encode viral proteins other than middle-T; and second to know how the transformed cell lines generated stable cytoplasmic mRNA encoding middle-T

protein from the modified genome in pPyMT1. Previous reports²⁵⁻²⁷ had suggested that RNA splicing is an obligatory step in the expression of genes which normally contain intervening sequences. We therefore thought it possible that the transformed cell lines always contained viral genomes integrated such that the early region and a host intervening sequence could be co-transcribed. However, because several genes in higher eukaryotes are known to express unspliced transcripts as stable cytoplasmic mRNAs²⁸⁻³⁰, a direct mode of expression could not be discounted.

The S₁-gel mapping experiments shown in Fig. 5 (see legend for details) clearly established that, in three of the four pPyMT1transformed lines examined, the principal mRNAs had 5' termini mapping in the same position (around nucleotide 150; 73 map units) as those of productively infected cells or other cell lines transformed by genomic viral DNA^{11,31}, and that these mRNAs were colinear with the pPyMT1 DNA sequence throughout the region encoding the middle-T protein. This demonstrated that none of the usual splicing events had occurred. Three of the transformed lines also produced variable amounts of a transcript beginning somewhere in vector or host DNA sequence 5' to the early region, which was also unspliced. In other experiments not presented here, we used a 3'-labelled single-stranded DNA probe to detect specifically splices originating from the donor used in the large-T mRNA (see Fig. 1); control, but none of the pPyMT1-induced, cell lines used this

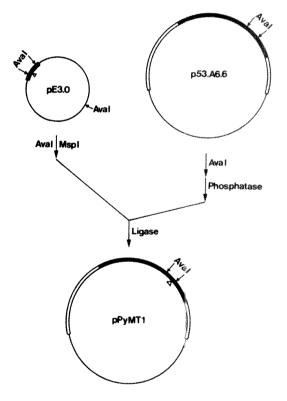

Fig. 2 Construction of a modified polyoma virus early region encoding only the middle-T protein. Plasmid pE3.020 consists of a partial cDNA copy of the middle-T protein mRNA (solid bar) inserted at the PstI site of plasmid pAT153⁴⁵. The absence of the intervening sequence is indicated by A The absence of the intervening sequence is indicated by \triangle . Plasmid p53.A6.6 consists of a complete wild-type Py genome inserted via the unique BamHI site into a derivative of pAT153 in which the plasmid AvaI site had been removed by cleavage with AvaI, S, nuclease treatment and recyclization. The Py early region is shown as a solid bar and other Py sequences as open bars. Plasmid pE3.0 was digested with AvaI+MspI. Plasmid p53.A6.6 digested with Ava I was treated with calf intestine alkaline phosphatase46 . The enzyme was inactivated by heating at 70 °C for 1 h, and the DNA used for ligation without further treatment. Equimolar amounts of the two plasmid digests were ligated at 25 µg mi⁻¹ p53.A6.6. After transfection into E. coli HB101, ampicillin-resistant colonies were picked and plasmid DNAs prepared⁴⁷. Recombinants were analysed for the substitution of the Py genomic Aval fragment by the pE3.0 cDNA Aval fragment using restriction endonucleases AvaI, AvaII, HinfI and MspI. One recombinant with the appropriate restriction map, pPyMT1, was chosen and large quantities of its DNA prepared⁴⁷.

[†] Transformed cells $(5 \times 10^2 \text{ and } 5 \times 10^3)$ were grown in DMEM, 5% FCS, 0.3% (w/v) agar. Microscopically visible colonies were counted after 14 days. Results of two independent assays are listed, done after extensive passage of the cell lines in culture (first number) or shortly after the original foci had become established as cell lines (second number).

[‡] Cells (5×10^5) were plated on 50-mm dishes and grown in DMEM/5% FCS, with medium changes every 24 h after the third day. The control F2408 cultures reached the indicated density at day 4 and increased no further. All transformed lines continued to divide until the cells came away from the plastic; thus the numbers listed are minima.

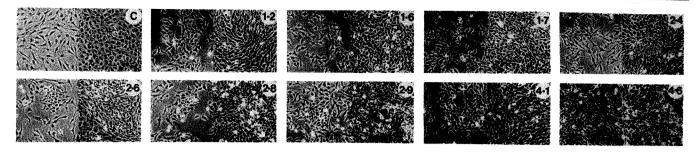

Fig. 3 Phase-contrast photomicrographs of pPyMT1- and p53.A6.6-transformed rat cell lines. Lines 1.2, 1.6, 1.7, 2.4, 2.6, 2.7 and 2.8 are pPyMT1 induced, 4.1 and 4.6 are p53.A6.6. 'C' is untransformed F2408 rat cells. Cells (5×10⁵) were plated on 50-mm dishes and incubated at 37 °C with DMEM containing 5% FCS for either 1 (left panels) or 4 (right panels) days.

splicing donor. Therefore, the only known early-region viral polypeptide which could be made from the mRNAs in pPyMT1-transformed cell lines is the middle-T protein.

The data shown in Fig. 5 also established that, at least in the two pPyMT1 lines mapped in detail (lines 2.4 and 2.8), viral mRNAs were produced which were colinear with the modified viral DNA sequence for the entire extent of the early region and had polyadenylated 3' ends mapping within viral sequence at the normal position. This strongly suggested, for reasons to be discussed below, that RNA splicing was not involved in the biogenesis of these messengers. Maps of the viral mRNAs produced by pPyMT1-transformed lines and by one p53.A6.6 line (4.6) are shown in Fig. 6. The third pPyMT1 line (1.2) examined in detail had mRNAs with 3' ends of colinear viral sequence which mapped within that portion of the early region which, in genomic DNA, uniquely encodes the C-terminal part of large-T protein. This has often been found in other Pytransformed rodent cell lines, and indeed is also the case with the one control line analysed here (line 4.6, see Fig. 6). It usually indicates the position of a virus-host integration junction 10,11 As such integration events remove the principal viral polyadenylation site, cell lines like 1.2 and 4.6 have often been found to produce relatively large amounts of mRNA terminating at the alternative viral polyadenylation site at 99 map units 10,20 illustrated in Fig. 6. One pPvMT1 cell line (2.8; see Fig. 6) also produced a continuous transcript of the L-DNA strand of the late region, extending from a 5' end at an undetermined point in the flanking vector or host DNA sequence to a polyadenylated 3' end mapping at the same position as that of late-region mRNAs produced in lytically infected cells.

The middle-T mRNAs synthesized by the pPyMT1-transformed cell lines 2.4 and 2.8, are identical in structure to the middle-T mRNAs produced during productive infection (Fig. 6). The mRNAs in the transformed lines, however, have not been spliced between their 5' ends and polyadenylated 3' termini. This strongly suggests that RNA splicing does not occur during the biogenesis of these messengers. We cannot rigorously exclude the alternative possibility, that the mRNAs derive from longer precursors which had been spliced and then subsequently processed to generate the 5' or 3' ends of the mature species, but we consider processing at the 5' end unlikely, because the ends detected are indistinguishable from those generated by normal use of the viral early promoter³¹; it is firmly established in several other systems^{32,33} that mRNA 5' ends correspond to transcriptional initiation points. We believe that cleavage and 3' polyadenylation after downstream splicing is equally improbable because polyadenylation has been shown to precede splicing during processing of Ad2 and simian virus 40 (SV40) RNAs^{34,35}. The efficiency with which the transformed lines produce cytoplasmic mRNAs may, however, be slightly impaired by the absence of splicing, as we have noted above that the transformation efficiency of pPyMT1 DNA is two to three times lower than that of the parental plasmid DNA. The level of expression obtained from integrated Py DNA has been shown to

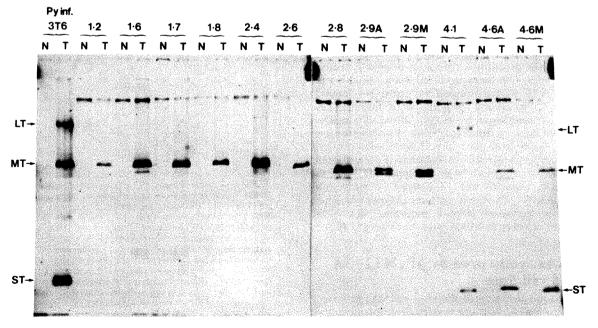

Fig. 4 Viral proteins synthesized by rat cells transformed by modified plasmid pPyMT1 (cell lines 1.2, 1.6, 1.7, 1.8, 2.4, 2.6, 2.8, 2.9A [after cloning in soft agar] and 2.9M, which had been cloned in Methocel) or by control plasmid p53.A6.6 (cell lines 4.1 and 4.6). Cultures grown in 50-mm plates were labelled with 35S-methionine (0.5 mCi per plate) for 3 h. Proteins were extracted and precipitated with Py anti-T protein serum (lanes T, immune serum; lanes N, non-immune serum) as described previously¹; they were then fractionated on 15% SDS-polyacrylamide gels, using the viral proteins precipitated from Py-infected mouse cells as markers (M).

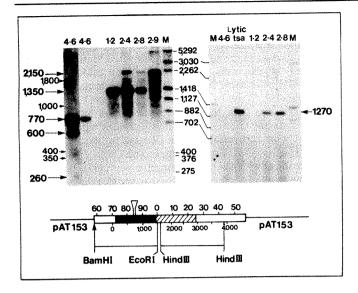

Fig. 5 Characterization of the viral mRNA in pPyMT1-transformed (1.2, 2.4, 2.8 and 2.9) and a p53.A6.6-transformed (4.6) cell lines by alkaline agarose gel electrophoresis of nuclease S₁-resistant hybrids. Experimental procedures were previously described⁴⁸ in detail. The diagram illustrates the structure of the Py DNA insert in the plasmids, with the middle-T proteincoding region in black, the remainder of the early region hatched and the restriction fragments used in the S1-mapping experiments indicated. The position of the deletion in pPyMT1 is also shown (∇). Left panel: S_1 resistant DNA from 100 µg of total cytoplasmic RNA from the indicated cell lines, hybridized to the unlabelled homologous DNA fragments extending from a BamHI to an EcoRI (58.0-100 map units; nucleotides 4,632-1,565; see diagram) site in plasmids pPyMT1 or p53.A6.6. After electrophoresis, the S₁-resistant DNA products were transferred to nitrocellulose and visualized by annealing to nick-translated viral DNA. The lane on the left is from a longer exposure of the same gel (on this exposure, the indicated 350nucleotide product was visible with the pPyMT1 transformants). Lane M shows Py restriction fragments run as size markers. The calculated lengths of S₁-resistant products are indicated to the left. Larger numbers refer to principal products. Smaller numbers refer to products resulting from S1 cleavage within DNA-RNA hybrids at 93 map units, a phenomenon always found in S₁ mapping of Py early-region mRNAs which is probably a methodological artefact²⁰. Product assignments are: lane/line 4.6: the 600and 260-nucleotide products represent the alternative 5'-colinear RNA segments, as shown in Figs 1 and 6; the 770-nucleotide product represents the 3'-colinear RNA segments, extending from the splice acceptors at nucleotides 795 and 809 to the end of the restriction fragment at 1,565; the minor 400- and 350-nucleotide products derive from the 770 by S₁ cleavage at 93 map units (~nucleotide 1,200). In lanes/lines 1.2, 2.4 and 2.8, the 2,150-nucleotide product represents a continuous transcript extending from the BamHI site to the EcoRI of pPyMT1 DNA; the 1,800-nucleotide product is the result of cleavage of the 2,150 at 93 map units; the major 1,350-nucleotide product represents a continuous transcript extending from the normal 5'-end position of Py early-region mRNAs (nucleotide 150; ref. 31) to the EcoRI site in pPyMT1 DNA; the minor 1,000- and 350nucleotide products represent cleavage of the 1,350 at 93 map units. Lane/line 2.9: pattern too complex for analysis. Right panel: polyadenylated cytoplasmic mRNA from the indicated transformed cell lines, or from mouse cells productively infected with Py thermolabile mutant sa^{20} , annealed to the unlabelled Py *HindIII* fragment illustrated in the diagram below. The transfer was annealed to a 32P-labelled probe48 which detects only transcripts of the E-DNA strand, and therefore the 1,270-nucleotide product maps the 3'-colinear segments of early-region mRNAs extending from the HindIII site (1.8 map units; nucleotide 1,650) to the previously determined polyadenylation site at 25.8 map units (~nucleotide 2,930). No bands were detected with RNA from cell lines 4.6 and 1.2 because the 3' ends of viral sequence in these mRNAs lie before (1.2) or shortly after (4.6) the HindIII site.

vary considerably among transformed cell lines, although each seems to use the viral early promoter¹⁰. This variation is probably a chromosomal position effect; similar observations have been made in avian sarcoma virus-transformed mammalian cell lines³⁶. Thus, we may have selected among the pPyMT1 transformants a subset of integrated genomes which are transcribed at a particularly high level to compensate for a defect in subsequent processing. Alternatively, the reduced trans_{D136} formation efficiency of pPyMT1 may have little to do with RNA₉₁₄₅

synthesis and instead reflect the absence of the small-T protein (see below).

To investigate this alternative, we have begun experiments comparing nuclear RNA with cytoplasmic RNA in the pPyMT1-transformed cell lines. We are also studying the expression of pPyMT1 DNA soon after transfection into rat cells; preliminary results indicate that the amount of viral cytoplasmic RNA synthesized from the modified genome is similar to that produced by unmodified DNA 60 h after DNA transfection, but better quantification is required to resolve the issue.

The production of stable, unspliced, cytoplasmic middle-T mRNA from the modified genome in pPyMT1 does not necessarily conflict with previous results^{25–27}. The conclusion that RNA splicing is obligatory could not be generalized from the few cases examined in these earlier experiments. Moreover, if instead of proposing that splicing in itself is essential, one hypothesizes that there is an RNA sequence, often but not always located within introns, which has a positive function in RNA maturation, all the available data could be accommodated. Given the pattern of differential splicing evolved by polyoma virus to produce three mRNAs from one precursor, it

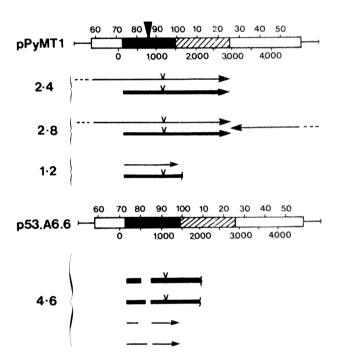

Fig. 6 Structures of Py mRNAs in pPyMT1- and p53.A6.6transformed rat cell lines, as deduced from S1-gel mapping studies such as those illustrated in Fig. 5 and other experiments (not presented) using one- and two-dimensional gel fractionation. The mRNAs are aligned below line diagrams of the viral DNA inserts in the plasmids used, but note that we have not determined the structures of the viral DNA actually present in the transformed cell lines. The middle-T protein-coding regions are shaded, and the rest of the early regions are hatched. mRNAs are represented by thick and thin lines to suggest their relative abundancies. The 5' ends of readthrough transcripts have not been mapped and are therefore indicated by dotted lines. Arrow heads are polyadenylation sites. The S₁-sensitive site at 93 map units is indicated by ♥. The 3' ends of viral sequence indicated by I probably represent the positions of virus-host joints, as frequently found in other Py-transformed cell lines 10. The four cell lines all contained detectable amounts of mRNAs ending at the 99-map unit alternative polyadenylation site 10,20, but these are only illustrated for lines 1.2 and 4.6 where they comprised significant proportions of the viral messenger. Note that in cell line 4.6 there must be mRNAs with the two different small splices (see Fig. 1) because this line produces both small- and middle-T proteins, but these cannot be distinguished by agarose gel analysis.

would not be surprising if such a sequence occurred somewhere outside the 63 nucleotides comprising the middle-T protein intervening sequence. This hypothesis would also better explain the expression of genes such as those for adenovirus protein IX2 and interferons 30 which lack introns, or the abundant production of unspliced late SV40 19S mRNA²⁸ in certain situations. The effect of deletion mutations interfering with the splicing of the SV40 small-T protein mRNA has also been investigated unspliced mRNAs were usually not expressed. It is possible, however, that most of the deletions caused preferential splicing of the precursor to yield large-T, rather than unspliced, mRNAs. Indeed, one deletion (dl 884) removing the small-T mRNA splice donor appeared to synthesize a truncated small-T protein, perhaps by translation of an unspliced messenger³⁷

Roles of polyoma virus early proteins in transformation

Our results strongly suggest that expression of the polyoma virus middle-T protein is sufficient to establish and maintain a transformed state. What of the other two viral early proteins? Viable deletion mutants (the hr-t mutants) have been isolated9 which synthesize normal large-T protein but no detectable small- or middle-T proteins^{4,38,39}. These mutants do not transform cells^{8,9}. Moreover, the integration of such DNA into the rat cell genome can result in cell lines which express the large-T protein but are phenotypically normal8. Deletion mutants lacking DNA encoding the C-terminus of the middle-T protein, but which encode normal small-T protein, are severely impaired in transforming activity⁴⁰, as are certain internal deletions mapping within the middle-T/large-T overlap region¹⁷⁻¹⁹ and a point mutant which causes premature termination of only the middle-T protein (D. Templeton and W. Eckhart, manuscript in preparation). These observations are consistent with our demonstration of the critical role of middle-T protein in transformation; they also suggest that expression of the small-T protein alone cannot transform cells. It is therefore clear that of the three early polypeptides, only individual expression of the middle-T protein can induce the dramatic changes in cell regulation identified as viral transformation. We found, however, that pPvMT1 DNA has a slightly reduced transformation efficiency, which may reflect either an impairment in middle-T gene expression or the absence of an additional gene product. It will be interesting to construct plasmids containing two modified early regions which

independently encode middle-T and one of the other T proteins and to determine whether any of these have a fully restored transformation potential. Furthermore, we have not vet systematically studied in the pPyMT1-transformed lines all relevant parameters of the transformed state. If the middle-T transformed lines prove to be different in some selectable property, it will be possible to assess the roles of the other T proteins by supertransfection with the appropriate cDNA recombinants.

Our results are in prima facie disagreement with the recent work of Cuzin and collaborators (Rassoulzadegan, M., Gaudray, P., Canning, M., Trejo-Avila, L. and Cuzin, F., submitted for publication) which suggested an involvement of the aminoterminal portion of the large-T protein in the maintenance of the transformed state. The disagreement may reflect differences in the way in which the transformants were obtained, although preliminary results indicate that pPyMT1 DNA does transform FR3T3 rat cells in the conditions used by these workers (F. Cuzin, personal communication). Collaborative experiments now in progress between the two laboratories using the plasmid DNA described here should resolve this issue.

The mechanism whereby middle-T protein causes transformation is unknown. Of the three polyoma virus T proteins, a unique property of the middle-T is its association with the plasma membrane 16,38, although efforts to detect it on the cell surface have been unsuccessful³⁹. Several groups have also found a protein kinase activity associated with the Py middle-T protein which results, in vitro, in the phosphorylation of a tyrosine residue in the middle-T protein itself⁴¹⁻⁴⁴. We tested four pPyMT1-transformed (1.2, 2.4, 2.6 and 2.8) and one p53.A6.6-transformed (4.6) cell lines for this kinase activity: they were all positive (data not presented), demonstrating that no viral protein other than the middle-T is required. However, it is not proved that the kinase is an activity of the middle-T protein rather than that of a bound host enzyme. Introduction of the modified viral early region from pPyMT1 into a bacterial expresion vector to obtain large amounts of the middle-T protein would therefore be important to produce a middle-T protein that could be used to assess directly whether it is a tyrosinespecific protein kinase and to assay other potential functions.

We thank Mrs Kit Osborne and Miss R. Smith for technical assistance. We are also grateful for the advice given by our colleagues at the ICRF, Mike Fried, Birgitte Lane, Natalie Teich and John Wyke, and thank Francois Cuzin for communicating his unpublished results, and Steve Dilworth for the gift of anti-T serum.

Induction of 8-azaguanine resistance and sister chromatid exchange in human lymphocytes exposed to mitomycin C and X rays *in vitro*

H. J. Evans & Vijayalaxmi

Medical Research Council, Clinical and Population Cytogenetics Unit, Western General Hospital, Edinburgh EH4 2XU, UK

Indirect evidence implies that 8-azaguanine-resistant (AG') lymphocytes in human periphera! blood are mutants associated with the loss of the hypoxanthine-guanine phosphoribosyltransferase (HPRT) locus on the active X chromosome, the mutation frequency increasing linearly with age. AG' variants are readily induced in lymphocytes exposed to mitomycin C in vitro, their incidence correlating with induced sister chromatid exchanges (SCEs). Although SCE events and the development of an AG' phenotype may reflect a common type of DNA damage, mitomycin C-induced AG' variants are not mutants but are suggested to be cells having a transcriptional block at the HPRT locus. AG' variants are also readily induced by X rays in vitro, their incidence correlates closely with the incidence of aberrations induced in the X chromosome and they are considered to have a mutational origin.

A MAJOR requirement in attempts to measure the effects of environmental agents in inducing mutations in man is the development of systems to measure induced mutation frequency in readily accessible human somatic cells. In man, the enzyme hypoxanthine–guanine phosphoribosyltransferase (HPRT) (EC 2.4.2.8) salvages hypoxanthine and guanine by conversion to their respective nucleotides, but the presence of this enzyme, which is coded for by an X-linked gene, is not necessary for cell proliferation and is absent, or defective, in males with the Lesch–Nyhan syndrome¹⁻³. The enzyme also converts purine analogues such as 8-azaguanine (8-AG) or 6-thioguanine (6-TG) to their respective nucleotides and, as these are cytotoxic, their incorporation results in cell death^{4.5}.

Strauss and Albertini⁶ used the cytotoxicity of 6-TG to human blood lymphocytes possessing normal HPRT, to distinguish and select for viable variant cells resistant to 6-TG (TG^r). Autoradiography indicates that such cells undergo DNA synthesis and survive in the presence of normally toxic levels of 6-TG following their exposure to the mitogen phytohaemagglutinin (PHA). The frequency of TG^r cells in lymphocyte populations from normal individuals was $\sim 1.3 \times 10^{-4}$ at a 6-TG concentration of 2×10^{-4} M, whereas in cancer patients being treated with cytotoxic (and mutagenic) drugs, their frequency was increased, in some cases up to 20-fold.

Small lymphocytes have scanty cytoplasm, a low metabolism and poor conversion of purine bases into nucleotides⁷. However, exposure to PHA initiates de novo purine synthesis and activates the purine salvage pathways⁸. It seemed possible therefore that exposure of lymphocytes to mutagens in vitro might also yield variant ('mutant') cells that would undergo blast transformation and remain viable on exposure to PHA and toxic purine analogues, in contrast to normal cells. We show here that the spontaneous frequencies of human lymphocyte variants resistant to 8-AG (AGr variants) increase with the age of the blood donor; that variant frequency is increased in a dosedependent fashion following exposure of human lymphocytes in vitro to the alkylating agent mitomycin C (MMC) or to X rays; that, for MMC, their incidence is related to the incidence of induced sister chromatid exchanges (SCEs) and, for X rays, is correlated with the incidence of gross chromosomal aberrations.

Rationale

One of the preliminary experiments undertaken to develop the protocol outlined below was a comparison of the response of lymphocytes to 8-AG and 6-TG (Fig. 1). The spontaneous incidence of purine analogue-resistant cells (defined by their

ability to undergo transformation by PHA and proceed through to a DNA replication phase) decreased with increasing analogue concentration, reaching a plateau at concentrations of $\sim 2 \times$ 10⁻⁴ M. Factors favouring the use of selection in 6-TG rather than 8-Ag ^{15,16} were: differences in the stability of the two analogues ^{9,10}, the higher affinity of 6-TG than 8-AG for the substrate HPRT ^{11,12}, the influence of exogenous purines present in serum in reducing the selection pressure exerted by 8-AG, but not 6-TG ^{10,13}, and the fact that many mammalian cell mutants retrieved following selection in 8-AG may retain almost normal levels of HPRT whereas virtually all mutants following selection in 6-TG are HPRT (refs 14, 15). Nevertheless, similar mutant expression times and rates of spontaneous and X ray-induced mutations to AG^r and TG^r have been reported for human diploid fibroblasts¹⁷. In our study we were strongly influenced by the fact that 6-TG is incorporated into DNA^{5,18} and that inhibition of DNA synthesis by excess thymidine protects against the toxicity of 6-TG, but not of 8-AG³. In contrast, 8-AG is incorporated into RNA^{5,19}, and inhibition of RNA synthesis protects against the killing effects of 8-AG, but not 6-TG. The short-term culture of lymphocytes in vitro is inappropriate for selecting for resistance to cell killing after DNA synthesis, because the cells have a limited proliferation potential in vitro and colony-forming assays are not possible. In view of this, and because PHA-induced lymphocyte blast transformation requires considerable RNA synthesis, we used 8-AG $(2 \times 10^{-4} \text{ M})$ rather than 6-TG in all the experiments reported

Incidence of AG^r lymphocytes in relation to donor age and sex

The incidence of AGr lymphocytes was determined in blood samples from 26 healthy donors (14 male) aged 16-82 yr (Fig. 2). The variant frequency ranged from 0.80×10^{-4} to 3.99×10^{-4} and despite considerable scatter, there is, nevertheless, a clear age dependence: a similar scatter, but no obvious age dependence, was noted by Strauss and Albertini⁶. There was no evidence of any significant effect of sex ($t_{24}=0.76$, P>0.10) and Kendall's²⁰ coefficient of rank correlation for the pooled data was $y=0.325\pm0.140$ (t=2.33, P=0.02), indicating a significant age effect. The slope of the fitted line of least squares gives $b=0.0294\pm0.0099$, so that the AGr variant frequency increases by $\sim 3\pm1$ cells per 10^6 cells per yr. Interestingly, the two highest yields in the <45-yr age group were from blood samples from cigarette smokers, but almost equivalent yields

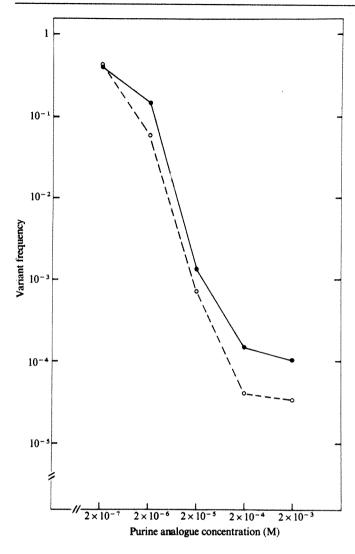

Fig. 1 The incidence of purine analogue-resistant variants in lymphocytes cultured in the presence of various concentrations of 8-azaguanine () or 6-thioguanine (O). In these and the other reported experiments, lymphocytes were separated by underlaying 3-ml aliquots of heparinized whole blood with 8 ml of Ficoll-Hypaque (10:5:2 of 12% Ficoll, 34% Hypaque and distilled water) and centrifuged for 15 min at 600 g. The WBC layer was removed, washed twice with phosphate buffered saline and the cells resuspended in RPMI 1640 medium with 12.5% fetal calf serum, 1.8% PHA (Wellcome), 1% glutamine, 100 μg streptomycin and 100 U pencillin. Duplicate sets of 5-ml cultures containing 2-3 \times 10⁶ lymphocytes were set up, one with and one without 8-AG or 6-TG, and incubated at 37 °C for 40 h. 3H -thymidine at 1 μ Ci ml $^{-1}$ (specific activity 18 Ci mmol $^{-1}$) was added to all cultures 12 h before collection. The procedure then followed that described by Strauss and Albertini⁶, including repeated syringing of resuspended pellets in small volumes of methanol/acetic acid (5:1) fixative using a 25-gauge spinal needle fitted to a 1-ml syringe to give free nuclei. Suspended nuclei were dropped onto clean microscope slides, air-dried and stained with carbol fuchsin (3% in ethanol) before being dipped in L4 liquid emulsion and exposed in the dark at 4°C for 72-96 h. As the work involved counting a considerable number of nuclei (up to 5 × 10⁶ in some experiments), use was made of an automated computer image analysis system to count the total numbers of nuclei on the slides to be scored and the coded slides were then analysed by one observer by high-power light microscopy to obtain a count for the number of labelled nuclei. For all paired treatments the incidence of labelled nuclei was then determined as a labelling index and the variant frequency (Vf) was calculated as

 $Vf = \frac{\text{labelling index in the presence of AG}}{\text{labelling index in the absence of AG}}$

were found in non-smokers and the limited numbers in our sample prevented any useful analysis of this parameter.

The incidence of 'spontaneous' and environmentally induced mutations in the somatic and germ-line cells of an individual would be expected to increase with increasing age and there is good evidence for an increased incidence of mutations transmitted to offspring in several studies on human populations^{21,22}.

Our results now provide evidence for an age-related increase in 'mutation' frequency in man's somatic cells. Ageing is associated with an increasing frequency of hypodiploid blood lymphocytes which in males consist largely of cells lacking the Y chromosome and in females of cells lacking an X chromosome, usually the inactive X 23,24. Ageing is also associated with smaller increases in the frequency of gross chromosomal structural aberrations (H.J.E., unpublished data), although aberration frequencies are of the order of 0.01 per cell whereas in ageing females more than 10% of the peripheral lymphocytes may be hypodiploid. Loss of an active X and consequent depletion of HPRT would result in the expression of an AGr phenotype. As the incidence of AG' lymphocytes is the same as between males and females, it seems more likely that a significant number of mutant AG' cells may be deficient for functional HPRT due to deletion or structural change at the HPRT locus. The gene is located in the terminal band (q27) of long arm of the X chromosome²⁵, so that all deletions involving this arm will result in the loss of the HPRT locus. If breakage sites are distributed between chromosomes in proportion to their length, 1/40th of such sites would be in the X chromosome in a male cell and some 60% of these would be in the long arm (Xq). With a deletion incidence of ~ 0.01 per cell, a deletion of the terminal region of Xq should therefore occur at a frequency of $\sim 1.2 \times 10^{-4}$ per cell, a value comparable with the observed incidence of AGr cells. In a study of G-banded chromosome preparations from individuals aged 60-90 yr we have identified a single Xq deletion in 2,131 cells—a frequency that again accords with the conclusion that the AG^r lymphocytes in vivo are probably cells with a deletion of Xa.

Induction of AG^r variants and SCEs following exposure to mitomycin C

Lymphocyte cultures were exposed to different concentrations of MMC for different time periods (see Table 1). Within each treatment time of 1, 5 and 10 h, the yield of MMC-induced AG' variants increased with MMC concentration, each doseresponse curve being of the form $y = \alpha + \beta d$, where y = variantfrequency, α = control frequency of $8.38 \pm 0.37~(\times 10^{-4})$ and $d = [\text{MMC}]^{0.33}$. Least squares analysis gave values of β_1 , β_5 and β_{10} , respectively, of 0.83 ± 0.21 , 0.92 ± 0.15 and 1.06 ± 0.13 . Although the product of MMC concentration and exposure time would, for certain combinations, be equivalent between the three sets of data, the effective concentration of MMC decreases with time in culture such that for a given variant frequency, a quadrupling of exposure time is equivalent to a halving of the initial concentration of mutagen. The maximum increase in AG' variant frequency is around 12-fold at the highest MMC concentrations, but significantly increased frequencies are evident following exposures to low doses, of the order of 10⁻⁸M, over short time periods.

The data obtained in the parallel cultures on SCE incidence (Table 1) show the very much higher frequencies of induced SCEs relative to induced AG^r variants per cell, but the shapes of the dose-response curves for the two end points are very similar. Least-squares analysis of the SCE data fitted to $y = \alpha + \beta d$ gave a value of $\alpha = 7.63 \pm 0.19$ and the slopes of β_1 , β_5 and β_{10} were, respectively, 0.53 ± 0.03 , 0.60 ± 0.03 and 0.81 ± 0.06 .

The similarities in the kinetics of response to AG resistance and SCE induction are shown in Fig. 3 where each datum on AG' variant frequency per cell has been multiplied by a factor of 7×10^3 and plotted against SCE frequency per cell. The resultant plot gives an excellent fit to a line of unit slope, indicating that for every induced AG' variant in the cell population there are some 7,000 induced SCE events. If the AG resistance involves an alteration on a single X chromosome, because that chromosome represents some 2-3% of the total chromatin per male cell²⁶, then for every event on an X chromosome that would result in an AG' cell there would be around 200 X-chromosome events that would yield SCEs. As SCE events may occur over almost the whole length of the chromosome, but

The cells used were separated lymphocytes from 10-20-ml samples of blood from a single donor exposed to MMC at the time of culture initiation. They were washed after treatment and transferred to fresh medium containing PHA, with or without 8-AG, for 40 h at 37 °C and treated and processed as described in Fig. 1 legend. To determine SCE frequencies, a third set of cultures was set up following exposure to MMC, using complete medium containing 25 µM bromodeoxyuridine and these were collected after 72 h and slides stained to give harlequin-stained chromosomes³⁸.

alterations at, or associated with, the HPRT locus to give an HPRT⁻ phenotype would be localized to only a small region, the numerical association between induced SCE events and AG variant induction is quite striking. This, however, does not imply a common mechanism for these two end points, but may simply reflect the fact that both types of event are consequences of the interaction of MMC with the cellular DNA.

Carrano et al.²⁷ have also reported a positive linear correlation between SCE and AG^r induction in Chinese hamster fibroblasts exposed to MMC: calculations on their data imply some 5×10^5 SCE events for each induced AG^r cell—a relative variant incidence some two orders of magnitude less than in the present human lymphocyte experiments. Studies on spontaneous mutation rates to AG^r in cultured human fibroblasts^{17,27}, and to TG^r in human lymphoblastoid cells²⁸, give values of $5 \times 10^{-6} - 5 \times 10^{-5}$ per cell generation, although both higher and lower values have been reported for other cell systems^{29,30}. The reported⁶ spontaneous frequency of TG^r lymphocyte variants of 1.3×10^{-4} and our values of $8 \times 10^{-5} - 8 \times 10^{-4}$ for AG^r variants seem too high to reflect mutational events at a single locus, but, as we have seen, they are consistent with the notion that many of these spontaneous variants lack part of an X chromosome.

Although the spontaneous AG^r variants may be a consequence of chromosomal aberration or loss, such changes cannot be responsible for AG^r cells induced following MMC treatment, because cells identified as AG^r are transformed by PHA and pass through the G₁ into the S phase, whereas normal

cells are blocked in G_1 . However, the development of chromosomal aberrations following exposure to MMC occurs during the S phase and not before it³¹; moreover, chromosome loss could only occur at mitosis, long after cells are identified as AG^r cells. Similarly, induced variants are not base loss or substitution mutants at the HPRT locus following misreplication of damaged DNA at the S phase, although such changes might occur following DNA misrepair in G_1 . What, then are these variants?

The true nature of the induced AG^x variants can only be clearly ascertained by studying their progeny: unfortunately, PHA-transformed lymphocytes normally have a limited lifespan in culture, so that this is not a practical proposition. However, there is a wide phenotypic diversity among purine analogueresistant mammalian cells embracing variants with different mutations at the HPRT structural gene, or in associated regulatory loci³², as well as unstable cells with high reversion rates and considered to be 'non-mutant'33. If the MMC-induced AG' lymphocytes are not true mutants, an appealing possibility is that they represent cells in which MMC alkylation had occurred at sites on the HPRT locus where the large MMC-guanine adduct prevented transcription of the locus to give functional HPRT—and hence allowed the cells to survive in the presence of AG. Some of these hypothesized transcriptional blocks could well lead to mutation following replication, but this is not necessarily so. The transcriptional block hypothesis is not easy to test, but one approach would be to examine the response to AGr induction in these G1 cells by other mutagens.

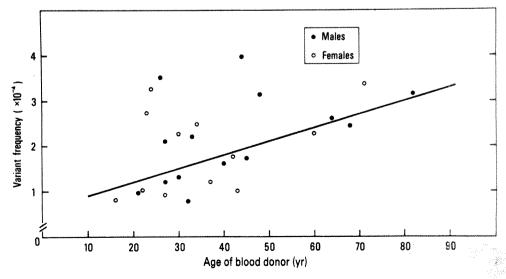

Fig. 2 AGr frequencies in blood lymphocytes of individuals of different ages.

Two separate experiments were carried out using separated lymphocytes from a single blood donor. The cells were exposed to a graded series of X-ray doses (at 183 rad min⁻¹ from a Siemens Stabilipan 300 kV; HVL 3.1 mm Cu at 12 mA with Thoraeus I filter) at the time of culture initiation, were transferred to fresh medium containing PHA, with or without 8-AG, for 40 h at 37 °C and processed as described in Fig. 1 legend.

Induction of AG^r variants following X-ray irradiation

Two groups 15,17 have studied the induction of TGr and AGr mutants following exposure of human fibroblast cultures to X rays and report similar linear dose-response curves and mutation rates of 2.1×10^{-7} and 3.1×10^{-7} per viable cell per rad. At 50 rad the mutation frequency was about twice the spontaneous level and at 200 rad was increased four- to sixfold. In an experiment on AG' incidence in X ray-irradiated lymphocytes (Table 2), we observed no significant increase following exposure to 50 rad, but did so at higher dose levels. The best fit to a linear dose response gave an induced variant rate of 1.25×10^{-5} per rad, but the data give a better fit to the power law function $y = \alpha + \beta d^n$, with n = 1.4. This curvilinearity was investigated further in a second experiment (Table 2) where the inclusion of additional dose points emphasized the curvilinear nature of the response, the data fitting a quadratic with negligible linear term, or a power law function with n = 2.1. Assuming

n=2, then $\alpha=6.90\pm0.11~(\times10^{-4})$ and $\beta=6.81\pm0.20~(\times10^{-4})$. The X-ray results show that: (1) significant increases in AG variant lymphocytes occur following exposure to quite low doses

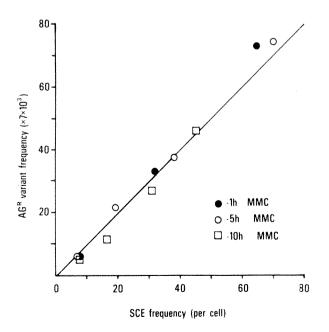

Fig. 3 SCE frequency per cell plotted against AG^r frequency per cell multiplied by 7×10^3 . The close fit of the experimental points to a line of unit slope indicates that over the range of doses and treatment times with MMC there are 7,000 SCE events for every single event resulting in an AG^r phenotype.

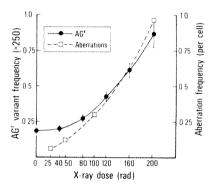

Fig. 4 AG' variant frequencies per lymphocyte versus X-ray dose (———) compared with aberration frequencies in X ray-irradiated lymphocytes (--—). The aberration frequencies are from Lloyd et al. 36 and include totals of fragments, centric rings and dicentrics, with the dicentric incidence doubled to account for equal numbers of undetected translocations (see ref. 37). The AG' frequencies have been multiplied by a factor of 250 for direct comparison with the aberration frequencies.

of X rays; (2) the dose response is curvilinear over 0-200 rad and approximates to a square law; (3) the kinetics of dose response for the induction by X rays of AG^r variant lymphocytes is remarkably similar to that for the induction of chromosome aberrations in lymphocytes (Fig. 4); (4) the rate of induction of AG^r lymphocytes is some 40 times that for AG^r fibroblasts, but is similar to mutation rates in human/hamster hybrid fibroblasts where mutant fitness does not influence mutant yield³⁴; (5) X ray-induced AG^r variants, in contrast to MMC-induced variants, are unlikely to be due to transcriptional blocks, but are more probably true mutations.

Cox and Masson¹⁵ have shown that some 40% of X rayinduced TG^r fibroblasts have stable X-chromosome aberrations (for example, deletions, translocations) whose location is consistent with the mapped position of the HPRT locus on the X chromosome. It seems probable therefore that most X rayinduced purine analogue-resistant mutants are associated with two types of gross structural change: those resulting in breakage of the X chromosome proximal to the HPRT locus, leading to loss of the gene at mitosis, and those resulting in breakage or damage directly at the locus itself. As the lymphocyte experiments involve no mitosis between X-ray irradiation and AG expression, direct damage to the HPRT locus seems the more likely. The relationship between the induction of chromosome aberrations in lymphocytes and X-ray dose is curvilinear35,36 with exchange aberrations increasing as approximately [dose]² and deletions as approximately [dose]^{1.4}. Much of the published data relate only to unstable aberrations, but in Fig. 4 published³⁶ dose-response data have been corrected to include all symmetrical interchange events, and the response curves for AG'

and aberration induction are seen to be similar in shape, with roughly one AG^r event for every 250 or so aberrations. Breakage sites are distributed in proportion to chromosome length so that some 2.5% occur in the X chromosome; thus, there are approximately six visible X-chromosome breaks for every variant induced. Our own studies of the total aberration spectrum in G- and R-banded lymphocyte chromosomes³⁷ from cells exposed to 200 rad of X rays reveal 150 breakage points in every 100 cells. At this dose there are 35 AG variants in 104 cells, or 35 variants per 15,000 breaks, that is, ~10 visible Xchromosome breaks for each variant.

Concluding comments

We have shown that the incidence of peripheral blood lymphocytes resistant to normally toxic levels of 8-azaguanine (AG' cells) increases with the age of the blood donor, is independent of sex and may well reflect the presence of cells with deletions of the terminal region of the X chromosome which contains the HPRT locus. In vitro exposure to MMC markedly enhances the incidence of AG' lymphocytes in a dose-dependent fashion and the rate of increase parallels the increasing incidence of induced SCEs. The high frequency of these MMC-induced AG^r cells and the fact that purine analogue resistance is expressed before the

cells pass through a DNA replication phase, argue against a mutational origin for these cells. Their close correlation with the induction of SCEs is, however, considered to indicate that both AG' and SCE induction by MMC are a consequence of interaction of the mutagen with DNA and it is suggested that the AG' variants simply represent cells in which the large MMC-guanine adducts have prevented normal transcription of the HPRT locus to give functional HPRT.

 $\bar{\mathbf{X}}$ -ray damage, which does not require misreplication at the S phase to result in mutational change, is also effective in yielding AGr cells. The dose response in vitro is curvilinear and is very similar to that for X-ray-induced chromosome aberrations in lymphocytes. As chromosome, or fragment, loss cannot intervene between the time of irradiation and the expression of the AGr phenotype, it is argued that X-ray-induced AGr cells may be true mutants and our evidence indicates that for every induced AG' event in a cell population there are about 10 visible induced breaks in an active X chromosome.

Finally, we note that the methods used to detect and count purine analogue-resistant variants in human lymphocyte populations are amenable to automation by flow cytometry, so that this approach may offer a powerful method for studying the effects of mutagens on human cells.

Immunocytochemical localization of glutamic acid decarboxylase in monkey striate cortex

Anita E. Hendrickson*, S. P. Hunt* & J.-Y. Wu*

* Department of Ophthalmology, University of Washington, Seattle, Washington 98195, USA † MRC Neurochemical Pharmacology Unit, Cambridge CB2 2QH, UK ‡ Department of Cell Biology, Baylor College of Medicine, Houston, Texas 77030, USA

Neuronal cell bodies and synaptic terminals positive for glutamic acid decarboxylase, the enzyme responsible for synthesizing γ -amino butyric acid, have been located by immunocytochemical staining in all layers of the macaque monkey cortex. In layers II and III the staining pattern of periodic dots is identical with that seen in sections stained for cytochrome oxidase. The rows of dots run parallel with the ocular dominance columns, suggesting that the labelled neurones are preferentially related to each eye.

γ-AMINOBUTYRIC ACID (GABA) functions as an inhibitory neurotransmitter in the mammalian cerebral cortex including the visual cortex¹⁻⁴. We have localized the GABA-synthesizing enzyme glutamic acid decarboxylase (GAD) in monkey striate cortex and mapped the distribution of neuronal cell bodies and synaptic terminals positive for GAD (GAD+). Primate striate cortex has the advantage of being precisely laminated and has well characterized inputs and outputs⁵. Standard light microscopic immunocytochemical techniques were used6, with an antiserum to mammalian GAD which has been extensively characterized⁷⁻⁹. We have found that all cortical layers contain both neurones and synaptic terminals which are GAD⁺, but in different quantities. No variation in the distribution or number of GAD⁺ terminals was found in layer IVC which would correspond to the ocular dominance columns¹⁰, but in layers II and III a 375-µm periodic repeat of GAD⁺ dots arranged in rows was found. When the same brains were histochemically stained for the mitochondrial enzyme cytochrome oxidase ^{11,12}, the laminar density and distribution of cytochrome oxidase staining was the same as for GAD and an identical pattern of dots in rows was found in layers II and III.

Experimental procedure

Primary visual or striate cortex from four normal *Macaca fascicularis* monkeys was studied. In one animal the left eye was injected with 3 mCi of a mixture of ³H-proline and fucose 14 days before the animal was killed, to label the cortical ocular dominance columns by transynaptic transport¹⁰. In two animals the striate cortex received 1- μ l injections of colchicine (10 μ g μ l⁻¹) 1 day before they were killed to increase the GAD content of the neuronal cell bodies¹. GAD immunocytochemical and cytochrome oxidase staining methods are described in the legends of Figs 1 and 2.

In sections cut perpendicular to the cortical surface (Fig. 1b), the layers were strikingly outlined in the anti-GAD-incubated sections; sections incubated without specific anti-GAD serum showed no staining (Fig. 1a). All layers contained GAD staining

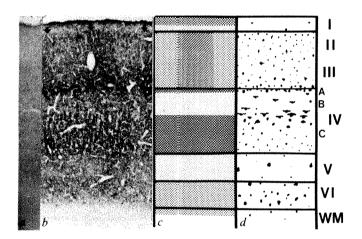

Fig. 1 Macaca monkey striate cortex with the layers numbered according to Lund¹³ on the far right of the figure. All monkeys were deeply anaesthetized and then perfused intracardially with phosphate-buffered 4% paraformaldehyde, pH 7.4, or a phosphatebuffered mixture of 4% paraformaldehyde, lysine and sodium periodate, pH 7.4. The brain was postfixed for 4-24 h, small pieces of cortex were sunk in 30% sucrose in phosphate buffer and serial frozen sections cut both perpendicular and parallel to the cortical surface. For immunocytochemistry, sections were incubated at 25 °C overnight in anti-GAD serum^{7.8} diluted 1/150 in phosphatebuffered saline, pH 7.4 containing 0.3% Triton and 1% normal sheep serum. This saline mixture was used subsequently for all antisera dilutions. After thorough rinsing, the sections were incubated in sheep anti-rabbit IgG serum diluted 1/10 for 30 min at 37 °C, and then in rabbit peroxidase-antiperoxidase⁶ diluted 1/50 for 30 min at 37 °C. The peroxidase was visualized by reacting the sections for 20 min at 25 °C in diaminobenzidine and hydrogen peroxide. Some sections were then lightly counterstained with thionine. Control sections were identically processed with the specific anti-GAD serum replaced by normal rabbit serum. a,b, Frozen sections processed for immunocytochemistry where the primary serum incubation used was (a) normal rabbit serum or (b) specific anti-GAD serum. In b all layers contain GAD synaptic terminals, but the amount varies between layers. In layers II and III periodic 375- μ m variations in density (b, arrows) are found. ×39. c, Schematic representation of the differences between layers in the density of GAD⁺ synaptic terminals. d, Schematic representation of the laminar distribution of GAD+ neuronal cell bodies; this drawing is based on many different sections from colchicinepretreated cortex.

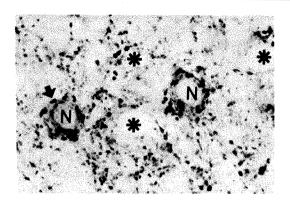

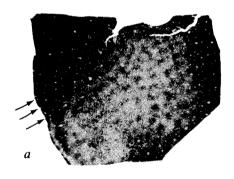

Fig. 2 Photomicrograph from layer IVC in a section reacted with specific anti-GAD serum. Many cell bodies do not stain (*) but are outlined by GAD⁺ terminals. Two GAD⁺ cell bodies show stained cytoplasm but an unstained nucleus (N) and are surrounded by GAD⁺ terminals (arrows). The neuropile also contains many GAD⁺ beaded processes and terminals. ×840.

but the intensity of labelling varied with the layer. The shifts in density corresponded to the laminar boundaries^{5,13} identified in thionine-stained sections. Under higher power (Fig. 2), the GAD staining was localized to cell bodies, beaded processes and small round densities which resembled synaptic boutons. Ribak¹ has shown in electron micrographs of GAD-stained rat visual cortex that these densities are synaptic terminals synapsing on cell bodies and dendrites. Because our preliminary electron microscopy has confirmed this finding for the monkey, we shall provisionally call these small densities terminals. There was no difference in laminar staining of central to mid-peripheral retinal representation in cortex; far-peripheral cortex was not examined.

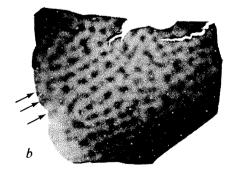

Fig. 3 a, A section cut parallel to the cortical surface passing through layers II and III which has been reacted in specific anti-GAD serum. An orderly pattern of dots aligned into rows can be seen (arrows). $\times 8.5$. b, An adjacent section stained for cytochrome oxidase by a 16-h incubation at 37 °C in phosphate-buffered diaminobenzidine and cytochrome $c^{11,12}$, pH7.4. The same pattern of dots aligned in rows is found. Compare the rows marked by the arrows in the two sections; $\times 80\%$ of the dots in these two sections directly superimpose on one another. $\times 8.5$.

Distribution of GAD⁺ terminals

As judged by both eye and photodensitometry, the upper halves of layers I, IVA and IVC were the most heavily labelled, II, III and VI slightly less so, and lower I, IVB and V were quite lightly labelled (Fig. 1b,c). The labelling in layer I was uniformly distributed and consisted of small, round GAD+ terminals in no obvious pattern. In all the other layers the labelling showed two patterns: GAD+ beaded processes run parallel or perpendicular to the cortical surface, and GAD+ terminals encircle both unstained and GAD+ cell bodies (Fig. 2). Most of the GAD+ terminals are ~ 1 μm in size, but occasionally there are clusters of much larger, 3-5-µm terminals. GAD+ terminals continue at least 50 µm into the white matter below the most inferior layer VI neurones.

Some GAD-reacted sections from the ³H-proline and fucose eye-injected monkey were coated for autoradiography, using Kodak NTB2 emulsion and 3-4-month exposures. Ocular dominance columns were apparent in layer IVC, but no

Fig. 4 Sections of striate cortex cut parallel to the cortex surface from the monkey whose left eye had been injected intravitrally with 3 mCi of equal parts ³H-proline and fucose 14 days before it was killed. The sections were first stained for cytochrome oxidase and then processed for autoradiography. In a the labelled ocular dominance columns from the left eve are visible in the dark-field photomicrograph as periodic repeats in IVC. In b this bright-field picture shows the same cytochrome oxidase-stained section. Layer IVC is darkly stained. Layer III and above contains periodic rows of dots. c, A drawing based on a short series of these doubly processed sections. Layer IVC contains alternating left evelabelled (solid black), right eye-unlabelled (white) ocular dominance columns. Beginning at layer IVA rows of cytochrome oxidase (or GAD⁺) dots lie at regular 350-400-µm intervals. The rows are schematically represented here; rows related to labelled columns are solid lines while rows related to unlabelled columns are dotted lines. There is one row for each column, running parallel to the axis of the column approximately along its centre. The three ocular dominance columns marked by arrows each became a continuous band in this series; all three ran parallel to the rows of dots. The ocular dominance columns and rows of dots related to the unlabelled eye were stained slightly darker in this monkey, possibly indicating some complication in the eye injection which was reflected by decreased cytochrome oxidase activity in cortex.

differential density of GAD+ terminals could be seen at either the column edges or centres, confirming the results from the other three animals. In all four monkeys a periodic repeat of GAD+ density was seen in layers II and III under low power (Fig. 3a; also see Fig. 1b arrows). This pattern consisted of fairly discrete dots arranged in rows formed by less dense connections between the dots. Along the rows the dots had a centre-tocentre spacing of $466 \pm 75 \mu m$ with the rows $378 \pm 55 \mu m$ apart. Under higher power it was apparent that the dots were formed by GAD⁺ cell bodies and a high density of GAD⁺ terminals. In adjacent sections stained for cytochrome oxidase (Fig. 3b), an

identical pattern of dots in rows was found. More than 80% of the GAD+ dots superimposed on the cytochrome oxidase dots in an adjacent section. When cortex sections from the 3H-proline/fucose eye-injected monkey were first stained for GAD or cytochrome oxidase and then processed for trans-synaptic autoradiography, the rows of dots in layer III ran parallel to the centres of the ocular dominance columns in layer IVC (Fig. 4).

Distribution of GAD⁺ cell bodies

Neuronal cell bodies have been considered to be specifically stained if they show an unstained nucleus with neuronal characteristics and a heavily stained cytoplasm with a sharp cellular outline (Fig. 2,N). In the two brains which received no colchicine, there were very few GAD+ cell bodies in layers I-IVC, but in layers V and especially VI, regularly spaced GAD neurones 15-20 µm in diameter were found. Small GAD+ cell bodies 8-10 µm in diameter lay in the lower edge of VI or in the white matter just under VI. In the two brains receiving colchicine injections, there was a striking increase in the number of GAD⁺ cell bodies, especially in layers I-IV. Even if our material is an underestimate because of the technical limitations inherent in these in vivo colchicine injections, our experiments indicate that monkey striate cortex contains many GAD+ neurones ranging in size from 9 to 30 µm. GAD neurones occur in every cortical layer and most appear to be various types of stellate neurone. Their distribution is schematically presented in Fig. 1d. In all layers some GAD+ neurones receive GAD+ terminals onto their cell bodies or dendrites. Most unstained cell bodies are outlined by GAD+ terminals in all layers.

Conclusions

Three findings emerge from this study. (1) The striate cortex of Macaca monkeys is very rich in both GAD⁺ cell bodies and synaptic terminals. Unlike rat visual cortex¹, there are clear laminar differences in the distribution of both GAD cell bodies and synapses. (2) There is a striking similarity between GAD distribution and cytochrome oxidase staining. Wong-Riley^{11,12} first pointed out the good correlation between cytochrome oxidase staining, GABA or GAD content and iron concentration in regions like cerebellum and basal ganglia. She suggested that inhibitory GABAergic cells are mitochondria-rich, energy-dependent cells which stain especially heavily for the haem enzyme cytochrome oxidase. This agrees with an earlier study14 where the nerve terminals which became labelled after exposure of rat brain homogenates to ³H-GABA were characterized by a high density of mitochondria within their cytoplasm. Our data support these suggestions and provide more direct evidence that cytochrome oxidase staining may be largely localized to GABAergic neurones. (3) The cytochrome oxidase and GAD⁺ pattern of rows of dots in layers II and III is identical to that shown in Macaca striate cortex using 2-deoxyglucose labelling15 in which similar rows of dots are parallel to the ocular dominance columns. In this study, sections doubly processed for GAD or cytochrome oxidase and trans-synaptic autoradiography also reveal that each row of dots is aligned parallel to the centre of each ocular dominance column. It therefore appears that there are rows of GAD+ inhibitory neurones in supragranular Macaca striate cortex which may be preferentially related to each eye.

Measurements of a solar flare-generated shock wave at $13.1 R_0$

Richard Woo & J. W. Armstrong

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California 91109, USA

Most information on interplanetary shock waves generated by solar flares has come from in situ measurements near 1 AU and beyond $^{1-3}$, and little is known about the structure near the Sun. We report here the first measurements of the structure of wind speed, electron density and electron density fluctuations of a shock wave propagating through the acceleration region of the solar wind. The radio-scattering observations consisting of spectral broadening, mean phase and amplitude scintillations were made on 18 August 1979, 13.1 R_0 east of the Sun and near the ecliptic plane using the Voyager 1 2.3- and 8.4-GHz radio signals. The results show that the shock wave had a shock speed of \sim 3,500 km s $^{-1}$. When compared with the average speed based on its transit time to 1 AU, it is seen that substantial deceleration took place as the shock wave propagated outwards from the Sun, a result that is consistent with a blast wave $^{1.4}$.

Figure 1 shows the view of Voyager 1, which was 7.03 AU from the Earth, and the Sun as seen from the Earth on 18 August 1979. It is clear that the Voyager 1 radio path was ideally positioned for studying the shock wave which was apparently generated by a solar flare located at N 09 E 90 (ref. 5). The longitudinal extent of the interplanetary disturbance was large because the shock was measured 90° away near 1 AU by the ISEE-3 magnetometer at 05.50 UT on 20 August (E. J. Smith, personal communication). The average shock speed based on the transit time to ISEE-3 is 1,053 km s⁻¹. A type II radio burst associated with this shock wave was also tracked in the 30 kHz-2 MHz frequency range by the radioastronomy experiment on ISEE-3 (ref. 5).

The results presented here are derived from the bandwidth-reduced digitally recorded data of the 'open-loop' receivers at the 64-m NASA Deep Space station located in Goldstone, California⁶. The 2.3- and 8.4-GHz signals were recorded in bandwidths of 1 and 3 kHz. respectively. For studying the amplitude scintillations and mean phase, these signals were further reduced to 100 Hz using a digital phase lock loop procedure⁷.

The radio measurements and the inferred results are summarized in Figs 2 and 3, respectively. Shock arrival occurs at ~ 15.01 UT, and based on the transit time from the Sun to 13.1 R_0 , we obtain a shock speed of 3,509 km s⁻¹. The time histories of spectral broadening ^{8,9} of bandwidth B at 2.3 and 8.4 GHz for 1-min integration times are shown in Fig. 2a. B is the full width between frequencies enclosing half the area under the radio-frequency spectrum. The pre-shock bandwidth at 2.3 GHz is ~ 1 Hz and is consistent with previous measurements of the quiet solar wind ⁸. During shock passage the bandwidths increase

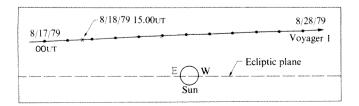

Fig. 1 View of Voyager 1 and the Sun as seen from the Earth on 18 August 1979.

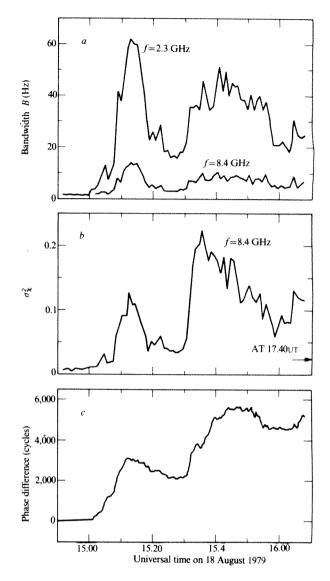

Fig. 2 Voyager 1 radio-scattering observations as a function of UT on 18 August 1979. a, Spectral broadening bandwidth B at 2.3 and 8.4 GHz. b, Variance σ_{χ}^2 of the log-amplitude scintillations at 8.4 GHz. The arrow shows the σ_{χ}^2 level at 17.40 UT. c, Difference between the 2.3 GHz and 3/11 of the 8.4-GHz phases.

considerably and two regions of enhanced bandwidth are observed. Although such transient events are rare during the solar minimum portion of the solar cycle⁸, they have been observed previously around the solar maximum^{9,10}. By examining the frequency dependence⁸ of B at 2.3 and 8.4 GHz we find that the average spectral index p of the three-dimensional power-law spatial wavenumber spectrum is 3.66 with a standard deviation of 0.11. The density spectrum, which is essentially Kolmogorov, is steeper than the quiet Sun spectrum for similar scales in this region of the solar wind¹¹, but consistent with other measurements during disturbed solar wind conditions¹⁰. Bandwidth increases are caused by enhancements in turbulence (electron density fluctuations) or acceleration of the solar wind⁸. These two effects can be separated by analysing the amplitude scintillations

The time history of the variance, σ_{xr}^2 of the log-amplitude scintillations at 8.4 GHz is shown in Fig. 2b. For weak scintillations ($\sigma_x^2 \ll 1$), σ_x^2 is related to the scintillation index m by $\sigma_x^2 = m^2/4$. The amplitude scintillations at 2.3 GHz are not

useful during shock passage because they are strong and saturated. The structure constant c_n of the refractive index fluctuations which characterizes the strength of the turbulence has been inferred from the 8.4-GHz scintillations and is shown in Fig. 3a. The corresponding scale for c_{n_e} , the structure constant for electron density fluctuations, is shown on the right. A spherical wave radio analysis has been used to interpret the scintillations 12. Before shock arrival c_n is assumed to vary as R^{-2} (R is heliocentric distance) along the radio path¹³. As the shock crosses the radio path, we assume that the contribution to σ^2 along the radio path outside the shock remains the same, and attribute the excess of the observed σ_x^2 to a uniform distribution of c, within the shock. The extent of the radio path traversed by the shock is defined by assuming that the shock is spherical in shape, emanates from the surface of the Sun and travels at a speed of $3,509 \text{ km s}^{-1}$. Figure 3a indicates that there are two regions of enhanced small-scale electron density fluctuations, corresponding to the two regions of increased spectral broadening. In these regions the turbulence representing scale sizes smaller than the Fresnel size (73 km at 8.4 GHz) increases by a factor of 3.7.

Two methods are used to deduce the solar wind flow speed (v) profiles shown in Fig. 3b. The log-amplitude scintillations are

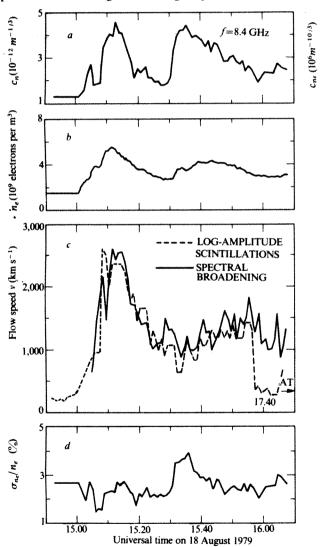

Fig. 3 Measurements of the shock wave inferred from the radio observations of 18 August 1979 shown in Fig. 2. a, Strength of turbulence as characterized by the structure constants c_n and c_{ne} of refractive index and electron density fluctuations, respectively. The results for c_n are for 8.4 GHz. b, Electron density n_e . c, Solar wind flow speed, v, as deduced using two methods (see text). The arrow corresponds to the flow speed measured at 17.40 UT. d, Ratio σ_{ne}/n_e in per cent, where σ_{ne} is the r.m.s. electron density fluctuation in scales smaller than the X-band Fresnel scale (73 km).

spectrum analysed in 1-min intervals so that velocity can be determined for these times from the location of the 'knee' or Fresnel cutoff using a spherical wave radio analysis 14. Although this method has considerable uncertainties when applied to quiet observations near the Sun because of the rounding of the knee due to fluctuations of the order of the mean11, it is useful in the case of the shock wave because the mean speed is large and velocity fluctuations are not significant. Generally, the correlation of multiple station intensity scintillations is the preferred radio method for measuring solar wind speed11,15. Near the shock front, two knees are present in the spectra, one due to the shock and the other to the slower ambient wind outside the shock. In these cases the higher velocity is always plotted. In a few instances around 15.00 UT, velocities could not be estimated due to the smearing of the knee by a rapidly rising velocity. At 15.58 UT the wind speed decreases quite abruptly. In this region the spectra again show two peaks. For these cases, however, the slower speed is chosen because it is clear from the level of the spectrum that it is due to a slowing of the flow speed along a radial cut through the shock and not to the slower ambient solar wind outside the shock.

The second method for estimating velocity involves using the measurement of σ_x^2 to remove the effect of turbulence from the spectral broadening observation in order to solve for velocity. This method requires that p be known. As this has been determined to be Kolmogorov, we can use the relationships that have been derived for a spherical wave ¹². The velocity profile inferred using this method is also shown in Fig. 3c. The agreement between the two independent methods is remarkable. When two velocities are present, the spectral broadening technique senses the faster one. This explains why this method gives correct estimates near the shock front but incorrect estimates beyond 15.56 UT.

As the shock crosses the Voyager radio path the flow speed rises sharply from 200 to 2,600 km s⁻¹, a factor of 13. Near the peak the velocities are fairly well determined and we estimate that the 2,600 km s⁻¹ measurement is accurate to within 20%. Elsewhere, the differences between the two curves in Fig. 3b probably represent the uncertainties in the velocity determination. Because the gross variation in velocity is substantial, it is easily recognizable and measured in spite of the uncertainties.

The final observation is phase at 2.3 GHz shown in Fig. 2c. This is formed by taking the difference between the S band and 3/11 (the frequency ratio of S and X bands) of the X-band phases¹⁶. During the phase lock loop procedures mentioned earlier, the S-band phase is non-coherently estimated using the X-band phase as a guide in the loop. In this way, any 2π ambiguities due to tracking errors are minimized. Because 'absolute' phase was not measured, Fig. 2c represents only the change in total electron content. We have deduced the electron density profile in Fig. 3b in the following manner. At 13.1 R_0 , we assume that the electron density $n_e = 1.5 \times 10^9$ electrons per m³. Before shock arrival we calculate the total electron content assuming a R^{-2} dependence for n_e . As the shock crosses the path we assume that the contribution to the total electron content outside the shock remains the same and attribute the excess of the observed electron content to a uniform distribution of n_e inside the shock. The extent of the shock is defined in the same way as that used for deducing c_n . Note that this inversion scheme used to obtain both c_n and n_e is most accurate near the shock front. Further back in the wake it becomes less accurate because, strictly speaking, c_n and n_e are not uniformly distributed along the radio path inside the shock. Nevertheless, it is a reasonable approximation and the general profiles for c_n and n_e should not be significantly affected. We note that the peak density increases by a factor of ~ 3.7 over the pre-shock value and is consistent with the theory for a strong shock 1,4. As expected for a shock wave, the peak in the turbulence characterized by c_n lags the peak in mean electron density.

Using the Rankine-Hugoniot relationships^{1,4}, pre-shock values of $n_e = 1.5 \times 10^9$ electrons per m³ and v = 200 km s⁻¹, post-shock values of $n_e = 5.5 \times 10^9$ electrons per m³ and

 $v = 2,600 \text{ km s}^{-1}$, we compute a shock speed of 3,500 km s⁻¹. which is consistent with the shock speed of 3,509 km s⁻¹ obtained from the transit time to 13.1 R_0 . According to time delay radio measurements¹⁷, electron densities in the solar wind at 13.1 R_0 may be as high as 3×10^9 electrons per m³. We have derived density profiles similar to Fig. 3b corresponding to 2×10^9 and 3×10° electrons per m³, and obtained shock velocities of 3,660 and 4,320 km s⁻¹, respectively. The fact that these shock speeds are higher than 3,500 km s⁻¹ indicates that some acceleration could have taken place between the Sun and $13.1 R_0$. This behaviour has been observed in white light coronograph measurements¹⁸, although shock speeds as high as 3,500 km s⁻¹ seem to be very rare 18,19. Questions do arise about the location of the shock fronts in the white light coronograph pictures 20 and simultaneous measurements with radio-scattering observations would be desirable. It is clear that the shock speed inferred from the Rankine-Hugoniot relationships has a rather high uncertainty because of two factors. First, the 20% accuracy in the flow-speed estimate translates approximately into a 20% accuracy in the deduced shock speed. Second, the uncertainty in the pre-shock electron density also leads to inaccuracy in the inferred shock speed. For example, by increasing the pre-shock electron density to 2×10^9 and 3×10^9 electrons per m³ we find that the shock speed increases by 5 and 23%, respectively.

We have plotted σ_{n_e}/n_e (σ_{n_e} is r.m.s. electron density fluctuations) in per cent in Fig. 3d. In this case σ_{n_e} has been computed for scale sizes smaller than the Fresnel size at 8.4 GHz (73 km). The fluctuations amount to several per cent before and after shock passage. It is interesting that this ratio shows a noticeable increase at about 15.35 UT. This represents the start of the second region of enhanced amplitude scintillations, and may correspond to the turbulent 'driver gas' of the shock wave. In contrast, the first region of enhanced amplitude scintillations corresponds to the compressed region of the shock wave.

The radio data end at about 16.08 UT before the completion of shock passage. However, some data were collected for a few minutes around 17.40 UT and yield a wind speed of 320 km s $^{-1}$ and $\sigma_x^2 = 0.0225$ at 8.4 GHz. These values, indicated by arrows in Figs 2b and 3c, show that the solar wind has almost returned to its pre-shock state.

It is clear that radio-scattering measurements using spacecraft radio signals complement similar measurements using natural radio sources21 and constitute a powerful tool for identifying and studying the detailed structure of coronal transients and disturbances. Plasma measurements of the 18 August shock wave were made by ISEE-3 at 1 AU. Information on shock speed beyond 13.1 R_0 but still close to the Sun will also be available from the ISEE-3 type II radio-burst observations. Future studies will correlate these measurements with the present results and will undoubtedly lead to an improved understanding of the evolution and deceleration of shock waves in the solar wind.

We thank M. Koerner, J. Randolph and J. Yuen for encouragement and support. We also thank the Voyager Radio Science and Radio Science Support Teams, and the Deep Space Network for obtaining these data, W. B. Kendall for valuable advice on the signal processing aspects of the data reduction, H. Hsu for help in the production phase of the processing, and H. V. Cane, M. Dryer, J. Gosling, M. Neugebauer and E. Smith for useful discussions. This paper represents research carried out at the Jet Propulsion Laboratory, California Institute of Technology, under contract NAS 7-100, sponsored by NASA.

Chemical composition of the atmosphere of Venus

V. A. Krasnopolsky & V. A. Parshev

Space Research Institute, Academy of Sciences. 117810 Moscow, USSR

Measurements onboard the Venera 11, 12 (refs 1-4) and Pioneer Venus^{5,6} spacecrafts stimulated us to study the chemical composition of the subcloud atmosphere of Venus in terms of the thermochemical equilibrium calculations, comparison of typical mixing and chemical times and a rule of heightindependent element mixing ratio in the absence of condensation7. The photochemistry of the atmosphere down to 50 km was calculated using transport effects and number densities of CO₂, H₂O, HCl, SO₂ and CO at the lower boundary and rate coefficients of 102 reactions. These reactions include catalytical cycles of COCl and COCl2 which accelerate O2 destruction and CO₂ formation. Altitude profiles of 27 components agree well with those measured in the upper and middle atmosphere. H2O and SO₂ mixing ratios are very similar and sharply decrease at 60 km due to SO₂ photolysis and sulphuric acid formation. Calculations show that sulphuric acid and sulphates are the main components of the second and third modes of particle size distribution in the upper and middle cloud layers. The lower cloud layer may consist of AlCl3 and FeCl3.

A model of atmospheric composition should produce vertical profiles of all atmospheric components from data on the abundance of parent molecules. This requires a knowledge of the chemical rate constants k_i , the values of temperature T and the eddy mixing coefficient K. As those constants are known in a few cases only, the number of components considered has to be limited and aeronomic analyses restricted to those parts of the atmosphere where these limitations apply.

The subcloud atmosphere (0-50 km) has a fairly high temperature and pressure (740 K and 90 atm near the surface) and is not exposed to solar UV radiation. Although thermochemical processes involving stable molecules dominate the region their rate constants are generally unknown. Hence we calculated only the thermochemical equilibria from the free enthalpy of the components. The comparison of the mixing times $\tau_m = H^2/K$ where H is the scale height, and of the chemical equilibrium, $\tau_c = (\sum_i k_i n_i)^{-1}$ where n_i is the concentration of a reagent considered, shows that mixing dominates chemical reactions in the whole lower atmosphere. The catalytic effect of the ground tends to accelerate chemical processes. For the order of magnitude comparison we used $K \approx 10^4$ $10^6 \text{ cm}^2 \text{ s}^{-1}$, $k_i = 10^{-10} \exp(-25,000/T) \text{ cm}^3 \text{ s}^{-1}$, mixing ratio $f_i \simeq 10^{-5}$; chemical processes on the ground were assumed to be accelerated by two orders of magnitude.

The atmospheric composition should then be approximately constant throughout the subcloud and can be determined by the thermochemical equilibrium near the surface (Qyama et al. assumed thermochemical equilibrium throughout the subcloud atmosphere). Calculations were based on the first data from Venera 11, 12 and Pioneer Venus experiments. The initial data chosen were concentrations of CO₂, N₂, SO₂ for which Soviet and US measurements had given similar results, concentrations of H₂O and S₂ (our estimate based on the spectroscopic

Table 1	The calculated com	position of the	subcloud atm	osphere of Venus

Mixing ratio f_i	0.96	3.4×10^{-2}	1.3×10^{-4}	2×10^{-4}	1×10^{-7}	1×10^{-6}	1×10^{-8}	1.5×10^{-5}	2×10^{-5}	3×10^{-7}	2×10^{-8}

measurements⁴), of HCl and HF from ground-based observations⁸. Our calculations are summarized in Table 1 (inert gases are not taken into account).

Components whose calculated mixing ratio was lower than 10^{-10} are not given in Table 1.

Our calculations and the related estimates are confirmed by further processing of the observational data. The height variation of $f_{\rm CO}$ was determined from Venera 12 data³ for which $f_{\rm CO}$ ranges from 3×10^{-5} above 36 km to 1.5×10^{-5} near the surface. Gas chromatography measurements on Pioneer Venus⁵ first indicated that CO was not present in the lower atmosphere, but then produced a similar dependence on height. Small amounts of $\rm H_2S$ and $\rm H_2$ initially suggested by Venera 12 data have not been confirmed, while the indication of COS seems reliable³.

Similar calculations based on the data of H₂O and O₂ mixing ratios measured by the gas chromatograph on Pioneer Venus gave an abundance of H₂SO₄ which was much higher than the bulk of the cloud layer.

We now consider the experimentally-obtained height dependences of mixing ratios. Here we take into account that if condensation is absent in a certain atmospheric region and if eddy mixing dominates the molecular diffusion, the relative abundances of elements should be height-independent. This enables the altitude dependences observed to be considered qualitatively.

The height dependence of CO might explain its gradual conversion into COS with decreasing height. The sum $f_{\rm CO}$ + $f_{\rm COS}$ = 3.5×10^{-5} agrees well with the spectroscopic measurements⁸ of CO near the top clouds; $f_{\rm COS}$ should decrease with height and be $\sim 10^{-6}$ above 36 km. Its decrease should be accompanied by a slight ($\sim 10\%$) increase of $f_{\rm SO_2}$ up to cloud deck. But in this case $f_{\rm COS}$ should be $5-10\times 10^{-6}$ at 22 km, which exceeds the upper limit of 2×10^{-6} obtained by the third sample of Pioneer Venus gas chromatography. Because the drastic variation of sulphuric compound abundance at 20–25 km recorded by the Pioneer Venus mass spectrometer⁶ was an experimental artefact it was ignored.

It is difficult to explain height variations of $f_{\rm H_{2O}}$ (2×10⁻⁴ in the cloud layer and 2×10⁻⁵ near the surface) deduced from the spectroscopic measurements on Venera spacecraft⁴. While spectroscopic measurements of $f_{\rm H_{2O}}$ seem more convincing than the data of Pioneer Venus gas chromatography⁵ where there could be perturbation effects from the spacecraft (values of $f_{\rm H_{2O}} = 1-5 \times 10^{-3}$ were obtained), we believe that errors in the measurements⁴ and the initial data used for interpretation do

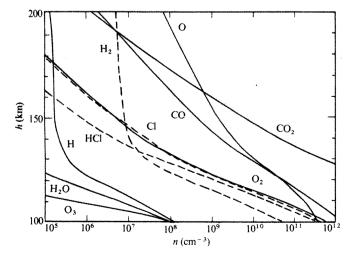

Fig. 1 Composition of the upper atmosphere of Venus. Dashed lines show the components for which the abscissa scale is enlarged 1,000 times.

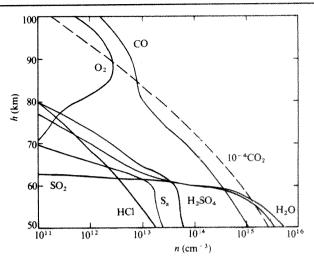

Fig. 2 Composition of the atmosphere of Venus between 50 and 100 km.

not preclude the possibility of $f_{\rm H2O}$ being independent of height. The other possibility is the presence of some hydrogen-bearing gas with mixing ratio $\sim 10^{-4}$.

We calculated the model composition in the atmosphere down to 50 km by solving a set of differential equations which describe the behaviour of 27 components (CO₂, H₂O, HCl, SO₂ and the products of their photolysis) involved in 102 reactions and include transport effects.

As our model takes into account both chlorine and sulphur compounds, the number of reactions compared with previous calculations⁹⁻¹¹ almost doubled. Our model uses an approximate description of the processes of radiation and matter transport in the cloud layer. We have developed a more universal method of imposing boundary conditions on daughter components, its special cases being photochemical and diffusion equilibrium.

We have considered not only chlorine oxides but also COCl and COCl₂ participating in cycles which are essential to O₂ destruction and CO₂ formation. Reactions of COCl and COCl₂ formation and removal and their rate coefficients¹² are shown in Table 2.

The reaction between H and Cl₂ provides the major sink for odd H* and Cl*. Our model also includes processes of sulphuric acid and sulphur aerosol formation from SO₂, four types of excited components and a long series of reactions.

Figure 1 shows the calculated composition of the upper atmosphere. The results of Pioneer Venus mass-spectrometric $^{13.14}$ and optical 15 measurements agree well with the calculations. Taking into account strong diurnal variability (our cacluations were made for solar zenith angle 60°) the comparison should be done for the altitudes at which CO_2 number densities are equal. Figure 2 shows the composition of the atmosphere and the cloud layer at 50–100 km, concentrations of many of minor components with $n < 10^{11}$ cm⁻³ are not included there. Figure 3 shows number densities of chlorine compounds. As we have not got room for a detailed analysis of all the components, we briefly describe some typical features of the H_2O , SO_2 , H_2SO_4 , aerosol sulphur S_a and O_2 distributions for which data are available.

The net photochemical transformation of SO₂ in the presence of H₂O can be described by

$$3SO_2 + 4H_2O \rightarrow 2H_2SO_4 \cdot H_2O + S$$

for 85% acid drops. Hence, the profiles of SO_2 and H_2O should be similar within most of the cloud layer and their concentrations at 50 km should differ by a factor of 1.3–1.8 for 80-85% acid drops. Our profiles agree well with measurements^{3,4} on

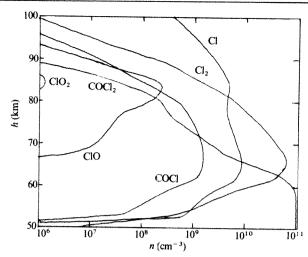

Fig. 3 Number density of chlorine compounds found in the atmosphere of Venus.

Venera spacecrafts and suggest that these measurements are correct and that H_2SO_4 formation is the basic drying agent in the above-cloud atmosphere.

Both profiles are determined by upward transport of SO_2 and H_2O from the subcloud atmosphere and their photochemical transformation into sulphuric acid drops through the SO_2 photolysis, SO_3 formation and absorption of H_2O . Analytically derived ratios and computations of H_2O and SO_2 number densities show that the eddy mixing coefficients should be $K = 2-5 \times 10^4 \text{ cm}^2 \text{ s}^{-1}$ at 50-60 km, to ensure a good fit with the spectroscopic ground-based and satellite measurements $^{16-18}$ of SO_2 and H_2O .

Eddy mixing determines not only H_2O and SO_2 number densities but also the amount of sulphuric acid: the higher K, the more H_2SO_4 should be in the cloud layer. The calculated amount of H_2SO_4 corresponding only to the second mode of the particle size distribution^{19,20} may be obtained for $K=100~\rm cm^2~s^{-1}$ which is not consistent with atmospheric dynamics and the observed SO_2 distribution.

A good agreement of the calculated values with the measured SO_2 number densities and the aerosol amount in the middle cloud layer may be obtained when $K=2\times10^4\,\mathrm{cm^2\,s^{-1}}$, in this case both the second and the third modes^{19,20} of particle size distribution in the middle cloud layer are dominated by sulphuric acid or the products of its further conversion (sulphates). For this conclusion, sulphuric acid must predominate drying in the above-cloud atmosphere.

Sulphur particles can constitute only a minor component of the cloud layer; their mass is an order of magnitude smaller than that of sulphuric acid and its products. The calculated concentration of sulphuric acid varies with height and is 80-87% at 55-70 km. The results of calculations are very sensitive to small variations of the $\rm H_2O/SO_2$ ratio at the lower boundary (50 km). A 10% increase of $f_{\rm H_2O}$ is followed by a sharp increase in humidity in the upper cloud layer, far beyond the limits of the ground-based spectroscopic measurements 14 ($f_{\rm H_2O}=10^{-(5-7)}$ at 62-65 km), by the much larger amounts of atomic hydrogen in the upper atmosphere.

The main paths of the formation of O_2 from atomic oxygen produced by CO_2 photolysis are the reactions

$$O+ClO \rightarrow O_2+Cl$$

 $O+O+CO_2 \rightarrow O_2+CO_2$
 $O+OH \rightarrow O_2+H$

Its destruction occurs through

$$COCl + O_2 \rightarrow CO_2 + ClO$$

 O_2 forms a layer 15-km thick at 90 km. The total amount of O_2 is 3.7×10^{19} cm⁻² which is a factor of 1.5 lower than the spectroscopic limit²¹. It is inversely proportional to K, hence $K \le$

 6×10^5 cm² s⁻¹ at 90 km. The above-cloud atmosphere cannot be a source of O_2 in the cloud layer where $f_{O_2} \simeq 4\times10^{-5}$, according to Pioneer Venus measurements⁵. The presence of such amounts of O_2 in the clouds should lead to another order-of-magnitude reduction of the aerosol sulphur abundance but it does not contradict the spectroscopic limit as the O_2 profile will be similar to the profiles of SO_2 and H_2O . However, this does not explain the appearance of O_2 in the cloud layer as the presence of O_2 is impossible in the lower atmosphere.

For the calculations and measurements to agree K must be 2×10^4 cm² s⁻¹ at 50-60 km, $K \le 6 \times 10^5$ at 90 km; the data on atomic oxygen in the upper atmosphere impose $K = 4 \times 10^6$ at Z > 110 km. At heights of 60-110 km the values obtained are well described by the dependence $K \sim n^{-1/2}$ which agrees well with the Pioneer Venus results¹⁴ and was assumed in our calculations.

The photochemistry of the atmosphere of Venus at 58-96 km was considered recently by Winick and Stewart¹¹. The main difference in input data between their model and ours is the absence of some chemical processes (53 instead of our 102 reactions); the most important of these are given in Table 2. The other difference is the assumption of height-independent H_2O mixing ratio $f_{H_2O} = 10^{-6}$ instead of $f_{H_2O} = 2 \times 10^{-4}$ at the lower boundary in our calculations, which shows very non-uniform distribution of H_2O (Fig. 2). Number densities of CO, O_2 , O_3 , SO calculated by Winick and Stewart¹¹ exceed the results of spectroscopic observations^{8,21-23}.

The X-ray fluorescence analysis 24 of the cloud-layer particles of Venera 11 and 12 indicated the presence of considerable amounts of chlorine ($\sim 2 \times 10^{-9}$ g cm $^{-3}$) in the aerosol. The presence of HCl drops is impossible because of the presence of sulphuric acid, and AlCl₃ is the most probable chlorine bearing material. If the Al₂O₃ abundance in the Venus lithosphere is similar to its abundance on Earth (15% in sediments), then the presence of HCl in the atmosphere implies a certain presence of aluminium chloride due to the heterogeneous thermochemical reaction

$$Al_2O_3 + 6HCl = 2AlCl_3 + 3H_2O$$

If its mixing ratio is 10^{-4} , it should be condensing at the lower cloud layer, and the calculated parameters of the layer (thickness, 2km; $\rho_{\rm max}=4\times10^{-7}~{\rm g~cm^{-3}}$ for $K=2\times10^4~{\rm cm^2~s^{-1}}$; size particle, 5 μ m) do not differ much from those measured ¹⁹.

Thus the third particle mode may have different composition in the middle and lower cloud layers. This is not a contradiction, because the nephelometer measurements²⁰ show that the middle cloud layer is very uniform and may have a photochemical nature while the lower cloud layer is variable and has a condensation origin.

The presence of chlorides in the cloud layer has recently been confirmed. The atmospheric albedo in the near UV is explained by the presence of two absorbers 18 : SO₂ and 1% FeCl₃ solution in the concentrated sulphuric acid. FeCl₃ condensation probably occurs near the lower cloud layer and the fine-fraction of the condensate with sizes of $\sim 0.5~\mu m$ moves through mixing in the upper cloud layer to act as sites of H_2SO_4 condensation. With

Table 2 Reactions of COCl and COCl₂ in cycles of O₂ destruction and CO₂ formation

No. Reaction	Rate coefficient (cm³ s ⁻¹ and cm ⁶ s ⁻¹ for two- and three- body reactions)
$ \begin{array}{lll} (1) & {\rm CO+Cl+CO_2} \to {\rm COCl+CO_2} \\ (2) & {\rm COCl+O_2} \to {\rm CO_2+ClO} \\ (3) & {\rm COCl+O} \to {\rm CO_2+Cl} \\ (4) & {\rm COCl+Cl_2} \to {\rm COCl_2+Cl} \\ (5) & {\rm COCl+Cl} \to {\rm CO+Cl_2} \\ (6) & {\rm COCl+CO_2} \to {\rm CO+Cl+CO_2} \\ (7) & {\rm COCl+H} \to {\rm CO+HCl} \\ (8) & {\rm COCl_2+O} \to {\rm CO_2+Cl_2} \\ \end{array} $	$3 \times 10^{-33} 2 \times 10^{-14} 10^{-13} 6 \times 10^{-13} \exp{(-1,400/T)} 6 \times 10^{-14} \exp{(-400/T)} 10^{-12} \exp{(-3,200/T)} 10^{-13} 10^{-14}$

this size ratio the resulting FeCl₃ solution concentration is close to 1%.

Thus aerosol particles in the upper cloud layer consist of drops of 80-85% sulphuric acid and a small amount of FeCl₃ (~1%). In the middle cloud layer the major components are sulphuric acid and its chemical conversion products such as sulphates.

The presence of nitrosylsulphuric acid²⁵ seems doubtful due to the smaller amount of lightning26 and its production of NO without further conversion to NO2, which needs large amounts

of HO2 and is necessary for nitrosylsulphuric acid formation. The lower cloud layer most probably consists of aluminium and iron chlorides. The presence of ammonium chloride is less likely as thermochemical calculations preclude the possibility of ammonia appearance in the lower atmosphere, and the photochemical formation of ammonia is highly unlikely.

Note added in proof: Further data on the temperature and position of the lower cloud layer preclude AlCl₃ being its main component.

Radiation-enhanced exhalation of hydrogen out of stainless steel

M. Ikeya*, T. Miki* & M. Touge†

*Technical College and †Faculty of Engineering, Yamaguchi University, Tokiwadai, Ube 755, Japan

The state and diffusion of hydrogen in solids have been studied extensively1,2, and the transport of hydrogen and its isotopes in metals has been found to involve classical diffusion and quantum effects such as tunnelling migration and small polaron hopping^{3,4}. The permeability and diffusion of hydrogen isotopes, particularly tritium (T), have been studied in a D-T fusion device5. Diffusion of tritium in the first wall of fusion reactor is expected to occur under high radiation fields due to plasma radiation, self β rays from the held-up tritium and neutroninduced radioactivity⁶. Heinrich et al. observed α -ray enhanced hydrogen permeation in an iron foil due to activated adsorption of the ionized hydrogen gas on the metal surface⁷. The γ -ray irradiation from a 1 mCi source, however, caused no appreciable change in permeation in 316 stainless steel⁵. No detectable loss of tritium was observed from a niobium sample containing 1% tritium⁸: the effect of the self β rays on tritium diffusion in niobium seems to be negative. We report here an experimental study of radiation-enhanced diffusion of hydrogen in hydrogencharged stainless steel using direct observation of hydrogen exhalation and lattice dilatation.

Hydrogen was charged into type 304 stainless steel of thickness ~100 µm by cathodic charging in 0.5 M H₂SO₄ solution at a current density of 30 mA cm⁻². Exhalation of gaseous hydrogen was detected using volume measurement of hydrogen gas bubbles by immersing the specimen in liquid glycerine and monitoring the increase of the liquid level in a glass microcylinder. Hydrogen bubbles on the surface were examined microscopically by coating the specimen with glycerine and hydrogen-induced lattice expansion was studied by X-ray diffraction. To enhance hydrogen evolution the X-ray tube was operated at 45 kV and 15 mA. The exposure rate of 30 ± 5 rad was determined with thermoluminescence dosimeters (TLD) of CaSO₄ taking the energy dependence of TLD into account. In some experiments γ -irradiation from a 60 Co source was also

Figure 1 shows the enhancement by X-ray irradiation of the gas exhalation rate out of stainless steel as a function of the time after 30 min of hydrogen charging. Exhalation rates, both with and without irradiation, decreased gradually with the time but the decrease was not monotonic presumably because of nonuniform distribution of hydrogen in the specimen. The exhalation rate of 4×10^{-6} cm³ cm⁻² s⁻¹ at 10 min is enhanced to 6×10^{-6} cm³ cm⁻² s⁻¹ by X-ray irradiation. The exhalation rate of hydrogen molecules deduced from the hydrogen gas volume exhalation rate is shown on the right coordinate of Fig. 1. The total volume of hydrogen gas exhaled was $\sim 3 \times 10^{-2} \text{ cm}^3 \text{ cm}^{-2}$ or 8 × 10¹⁷ H₂ cm⁻² indicating an initial average concentration of $\sim 1.6 \times 10^{20} \,\mathrm{H}$ atom cm⁻³ for a specimen $\sim 100 \,\mathrm{\mu m}$ in thickness—a number roughly two orders of magnitude smaller than that of f.c.c. unit cells.

Part of the hydrogen-charged specimen was covered with glycerine after the hydrogen exhalation had ceased and was exposed to X rays at room temperature. Hydrogen bubbles were observed on the surface of the specimen at the irradiated site as shown in Fig. 2a. No hydrogen bubble was detected at the non-irradiated site at this stage (Fig. 1b). The temperature of the same specimen was then raised to ~80 °C and new bubbles formed only at the non-irradiated site. Hydrogen atoms trapped and stabilized in stainless steel would have been released by X-ray irradiation.

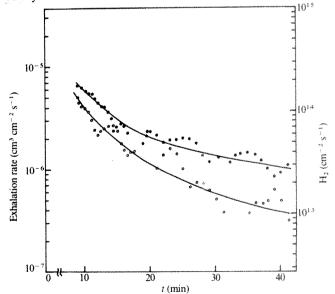

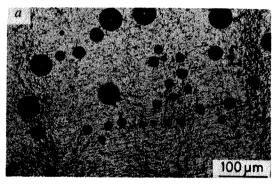

Fig. 1 The exhalation rate of hydrogen gas out of stainless steel 304 in liquid glycerine under X-ray irradiation () and without irradiation (O) as a function of time after the cathodic hydrogen charging in 30 min. The exhalation rate is enhanced by the radiation.

Hydrogen bubbles were not uniformly distributed on the specimen surface and their diameters were also random. The exhalation behaviour was different during irradiation; tiny bubbles appeared all over the surface and formed a 'film' of hydrogen gas on the surface. Presumably, exhalation from the grain surface by radiation-induced bulk diffusion dominates over grain boundary exhalation. No hydrogen bubble formed during X-ray irradiation if the stainless steel was not cathodically charged with hydrogen; confirming that the bubbles were not due to radiolysis of glycerine.

Enhancement of the exhalation rate of 2×10^{-6} cm³ cm⁻² s⁻¹ or 5.4×10^{13} H₂ cm⁻² s⁻¹ on exposure to X rays at 30 rad s⁻¹ indicates that $\sim 1.8 \times 10^{12}$ H₂ molecules are exhaled by 1 rad or $5 \times 10^{13} \, \mathrm{eV} \, \mathrm{g}^{-1}$. In terms of hydrogen atoms exhaled, $3.6 \times 10^{12} \, \mathrm{H \ cm^{-2} \ rad^{-1}}$ is greater than the number of the ion pairs produced by 1 rad in 0.03 cm³ gaseous hydrogen. The radiation energy absorbed by the 100-um thick stainless steel of density 8 g cm⁻³ is roughly 4.0×10^{12} eV for exposure to 1 rad. Thus, for one hydrogen atom exhalation the input energy was ~ 1 eV. The efficiency decreases so that ~4 eV per hydrogen atom exhalation is required 40 min after hydrogen charging. It is assumed that the probability of retrapping before hydrogen diffuses to the surface increases as the concentration of hydrogen is decreased. If the hydrogen concentration is high, the traps are almost all occupied by hydrogen. Most energy would be used to ionize the host stainless steel lattice atoms. The net energy absorbed at the unit cells with a hydrogen atom would contribute to causing the release of hydrogen in a cluster model, if the energy transfer process is absent. Thus, around 10^{-2} eV is required to detrap a hydrogen atom. It is not known how many retrapping and detrapping events are occurring, however, considering the high concentration, it seems that hydrogen comes out of stainless steel without an appreciable number of retrapping events. A similar radiation-enhanced exhalation rate of hydrogen out of stainless steel was observed on measuring pressure change with the specimen in an evacuated cell.

The lattice constant of a metal is increased by the dissolution of hydrogen. Figure 3 shows X-ray enhanced recovery of the lattice expansion measured from the shift of X-ray diffraction peaks for thin foils of the stainless steel with the thickness of

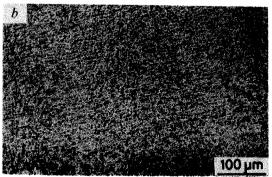

Fig. 2 Surface micrographs of electrolytically hydrogen charged stainless steel 304 coated with glycerine after 3.4 h ageing following the light charging for 5 min. a, Hydrogen bubbles induced at the irradiated site; b, no bubble was observed at the non-irradiated site.

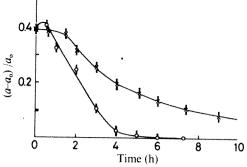

Fig. 3 X-ray enhanced recovery of lattice expansion induced by hydrogen in thin stainless steel foil. Fractional changes of the lattice constant determined from the X-ray diffraction peak are shown as a function of the time of X-ray irradiation (O) and of the ageing time for the non-irradiated specimen (X).

 ${\sim}35~\mu m$. The lattice expansion of ${\sim}0.4\%$ was decreased to 0.2% in ${\sim}4$ h and recovered in 12 h. On the other hand, it was reduced to 1.5 h for the fractional expansion to be the half and to 4.5 h for the complete recovery under X-irradiation. No hydrogen bubble was detected from the sample coated with glycerine after X-ray irradiation for 4.5 h although bubbles were still observed at the non-irradiated sample in agreement with the observation of the lattice expansion.

The lattice expansion persisted at 77 K without the X-ray irradiation for a long time. The X-ray or γ-ray irradiation at 77 K decreased the expansion and restored the lattice parameters. The result indicates that the hydrogen exhalation operates in the region where the monitoring X rays penetrate for the diffraction studies. The exhalation would not be caused by the radiation-induced decrease of the surface impedance at the surface barrier layer because the lowering of the surface impedance would not lead to the exhalation of hydrogen at 77 K where hydrogen is not mobile without irradiation. It also seems unlikely that specimens dipped in liquid nitrogen are heated by radiation. Thus, we conclude that the radiation has induced hydrogen diffusion in the bulk of the specimen. The present observation contrasts to that of Heinrich et al., in which surface impedance from gaseous hydrogen to the iron was found to be reduced by the α -ray ionization of hydrogen as in a permeation

It is still premature to assign the radiation-induced hydrogen diffusion a definite mechanism, but two possible mechanisms can be suggested tentatively. The electronic structure of hydrogen in metals has recently been calculated using a cluster molecule model involving the nearby metal electron orbitals. Hydrogen in metals also forms a stable quasimolecule, a diatomic complex, with C, N and O impurity on and with Ni in Fe-Ni alloys. Ionizing radiation might excite such quasimolecules or cluster molecules to antibonding or non-bonding states—such states were reported 1-2 eV above the valance band in studies of photoelectron emission and soft X-ray spectroscopy. Decomposition of the cluster might follow when antibonding or non-bonding states are reached. If this is the case, the input energy of ~1 eV per H atom exhalation was used effectively by some energy transfer process.

Destruction of the cluster or diatomic complex may also be explained by the core-hole Auger decay model for electron- or photon-induced desorption of gas molecules on the surface of solid¹⁴. However, the contribution of Auger process would be small considering the high efficiency of ~1 eV per hydrogen exhalation, and the model of cluster excitations remains the more likely explanation.

Energy transfer to hydrogen or to the proton by elastic collisions with photoelectrons and Compton electrons is also plausible. Like the electrotransport and heat transport mechanism for hydrogen migration², electron scattering at hydrogen causes a momentum transfer from electrons to hydrogen. No work has yet been done to prove the possibility of this

mechanism. However, it is conceivable that hydrogen is detrapped by the transfer of ~0.1-0.01 eV of energy from electrons by collisions.

The permeation rate was not affected appreciably by γ -rays from a 1 mCi source5. The dose rate in that case, assuming an average distance of 1 cm from the source, is only 10 rad h⁻¹, four orders of magnitude smaller than 10⁵ rad h⁻¹ in the present experiment. The 'hold-up' of tritium in the first wall of a fusion device is a severe problem. The hydride at the surface wall would be destroyed by radiation of the order of 10⁶-10⁸ rad h⁻¹ and also by the X-ray flux from the plasma. The reduction of tritium diffusion due to the blocking by transmutation-produced ³He (ref. 15) and to the trapping by defects or impurities might be compensated by the radiation-induced tritium diffusion. Further investigations are necessary to explain this radiation-induced hydrogen exhalation. Details of the X-ray diffraction studies will be published elsewhere with the result of isotope effects.

Expected immersion of Saturn's magnetosphere in the jovian magnetic tail

S. Grzedzielski, W. Macek & P. Oberc

Space Research Centre, Polish Academy of Sciences, Ordona 21, PL-01 237 Warsaw, Poland

Voyager 2 approaches Saturn (h) this month, August 1981, after the possible encounter^{1,2} of the planet with the tail or wake3 of Jupiter (24). With the magnetic flux in the tail of $\phi \cong 2 \times 10^{12}$ Wb (refs 4, 5) a simple model suggests that the tail is very long (7-15 AU) and wide enough (~0.6 AU) to engulf Saturn. This could result in a sudden drop (by a factor of \sim 40) of the ram pressure on the magnetosphere of Saturn. The ensuing inflation of the magnetosphere may cause effects observable from Voyager 2 and/or Earth-orbiting satellites, including a flare-up of kilometric radiation and enhancement of the Ly α limb brightening. Such events, if observed, could shed light on the magnetic and plasma nature of the jovian tail and on the electrodynamics of the saturnian magnetosphere.

The expected length of the jovian magnetic tail is 6-8 approx-

$$L_{t} = 2B_{1}r_{pc}^{2}/(\alpha B_{s}y_{c}) \tag{1}$$

where $2y_c$ is the width of the jovian magnetosphere at x = 0(centre of the planet, see Fig. 1 inset), B1, Bs are the ionospheric and the solar wind magnetic field intensities respectively, r_{pc} is the radius of the polar cap, and $\alpha < 1$ parameterizes the efficiency of reconnection⁷. Taking $y_c = 87 R_J$ (where R_J is the radius of Jupiter⁹), $B_1 = 1$ mT and $r_{pc} = 0.28$ R_1 (Voyager data^{4,5,10,11}), $B_s = 0.6$ nT (ref. 12) and assuming $\alpha = 0.1-0.2$ (as for Earth⁸) one obtains $L_t = 7-15$ AU. Thus, the jovian tail could be several times longer than the Jupiter-Saturn distance

Orbital considerations suggest that Saturn should miss the axis of the jovian tail by $\Delta \approx 380 R_{\rm J}$. This event (for a 400450 km s⁻¹ solar wind) would have been expected during the first week of May 1981. Immersion requires $\Delta < y(x_s)$, the half-width of the tail at Saturn's orbit (see Fig. 1 inset).

Recent Voyager 1 and 2 Jupiter flybys identified a tailwardoriented magnetic field (3-5 nT at $x_0 = 80-180 R_1$ (refs 5, 10, 11)) and two populations of circumjovian plasma: a cold one¹³⁻¹⁶ (densities¹³ $n \sim 10^{-5}$ cm⁻³) on the pre-dawn tail-like region of the magnetosphere, and a (denser, $n \sim 10^{-4}$ - 10^{-3} cm⁻³) hot plasma beyond $x \sim 160 R_{\rm J}$ streaming nearly antisunward¹⁷⁻¹⁹. Based on these data we have constructed a simple magnetohydrodynamical, one-dimensional model of the distant jovian tail.

We assume that the tail shape y(x) is determined by the condition of tail pressure equalizing total solar wind pressure

$$B_{s}^{2}/8\pi + p_{t} = m_{s}n_{s}v_{s}^{2}\cos^{2}\psi + p_{s} + (\mathbf{B}_{s} \cdot \hat{\mathbf{e}})^{2}/8\pi$$
 (2)

where $\hat{\mathbf{e}}$ is a unit vector ($\hat{\mathbf{e}} \perp \hat{\mathbf{n}}$ or $\hat{\mathbf{e}} \| \mathbf{B}_s$, where $\hat{\mathbf{n}}$ represents a unit outward vector normal to the tail boundary y(x), Fig. 1 inset).

The tail pressure consists of two components: magnetic $B_1^2/8\pi$ with the planetary magnetic field B_1 (and the plasma streams) parallel to the tail boundary y(x), and particle thermal pressure $p_t = 2n_t kT_t$. Conservation is also assumed of the magnetic flux, the mass flux, and the momentum

pure O were tried, see ref. 17).

The solar wind magnetic field pressure is due either to the tangential component only $(\hat{\mathbf{e}} \perp \hat{\mathbf{n}})$, which seems appropriate for v(x) in the ecliptic plane, or to the full field $(\hat{\mathbf{e}} | \mathbf{B}_s)$ which applies in the solar meridian plane. A standard Archimedean spiral model was used for \mathbf{B}_s (ref. 12) with a radial $(B_r \propto r^{-2}, r^2 =$ $(x+d)^2+y^2$, see Fig. 1 inset) and an azimuthal component $(B_{\varphi} \propto r^{-1})$. At Jupiter: $B_r = 0.08 \text{ nT}$, $B_{\varphi} = 0.58 \text{ nT}$. The solar wind is spherically symmetric with the thermal pressure p_s = $2n_s kT_s$, $(n_s \propto r^{-2})$, n_s (21) = 0.28 cm⁻³, T_s = constant = 0.25 × 10^5 K (ref. 12) and the ram pressure equal to $m_s n_s (\mathbf{v}_s \cdot \hat{\mathbf{n}})^2$, where $v_s = \text{constant} \approx 450 \text{ km s}^{-1}$ (ref. 12). Both the magnetic (tangential) pressure and the ram pressure depend on the angle of attack (defined in Fig. 1 inset: $\cos \psi = -\hat{\mathbf{v}}_{s} \cdot \hat{\mathbf{n}}$) which is related to the tail shape y(x) by the equation

$$dy/dx = \cot \alpha (\psi - \varphi), \quad \tan \varphi = y/(x+d)$$
 (4)

Equations (2)-(4) were numerically integrated for several cases given in Fig. 1 and Table 1, yielding y, v, n, T, p, B in the tail. The

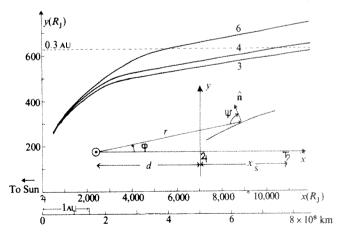

Fig. 1 Predicted boundary of Jupiter's distant magnetic tail in the jovicentric rectangular frame. The scale of ordinates is 10 times larger than the scale of abscissae. The shape of the tail was found by numerical integration of the pressure balance equation (2) for several cases, as shown in Table 1 and explained in the text. Assumed geometry is schematically shown in the inset. The most probable tail width (curve 4) at Saturn $2y_s = 1,212 R_J = 0.58 \text{ AU}$.

6	on	on		on	on		on	693	6.2×10^3	5.8×10^{-12}	1.0×10^{-13}

 $x_s = 9,170 \ R_J$ (1 $R_J = 71,398 \ \mathrm{km}$): half-width y_s of the tail (in R_J , 1 AU = 2,095 R_J), tail plasma flux $n_t v_t$, tail wind momentum flux $m_t n_t v_t^2$ $(m_t = \text{proton mass})$, tail thermal pressure $2n_t k T_t$, for various terms in equation (2), 'on' or 'off'.

For a long tail in a radial flow the ram pressure contribution vanishes for $x > x_f \sim 3,500 R_1$ ($\psi(x_f) = \pi/2$).

The approximation $\psi \to 0$ in equation (+) (total direction of the solar wind parallel to the sum-suprier (5-24) line) allows an analytical solution $y^3 - y_c^3 = 2.73x(x/2 + d)$ (x, y in R_1 , d = 10,900 R_1) leading to $y_s = 730$ R_1 ; this approximation is, however, not applicable to a wide tail.

For the cold plasma ¹³ (few eV, $n_{t0} \sim 10^{-5}$ cm⁻³) we assume the thermal to magnetic field energy density ratio β_0 to be $\sim 10^{-7} - 10^{-6}$. The hot ¹⁷ plasma (~ 30 keV and $n_{t0} \sim 3 \times 10^{-4}$ cm⁻³) has $\beta_0 \sim 0.3$ (at $x_0 = 184$ R_1 and $y_0 = 181$ R_2 , Voyager 1 and 2 data ^{5,10,13,17}).

For anisotropic plasma (CGL) one obtains a slightly lower value $y_s = 603R_1$.

integrations started close to Jupiter, at $x_0 = 50 - 200 R_1$ with $y_0 = 150 - 200 R_1$ (refs 5, 10). We assumed the plasma initially (at $x = x_0$) always isotropic with $v_t(x_0)$ equal to the local sound velocity.

Our calculations show that the tail width 2y_s at Saturn is large, of the order of 0.6 AU. Practically, this result is sensitive neither to the initial data nor to the details of the assumed model (see Table 1 and Fig. 1) and we suggest that Voyager 2 and Saturn will not miss the jovian tail. These unique events may shed light on several questions.

Penetration by Voyager 2 into the jovian tail may clarify two aspects of the gradual loss of identity by the tail: (1) merging of the tail and the interplanetary magnetic fields when the ratio ${\mathcal R}$ of field polarity reversal time scale to the time scale of the solar wind flow past the tail is 10^{-3} – 10^{-2} , in contrast to the terrestrial case when $\Re \ge 1$; the spatial scale of the inhomogeneities of the plasma in the tail should be of the order of $\Re y_s$; and (2) filling-up of the tail with the solar wind plasma through the open field lines and/or diffusion across the field. These processes should be well in progress at Saturn's distance although still far from completion²⁷. Thus information on the relative roles of these two aspects could be available well before NASA's OPEN programme²⁰

Inside the tail, Saturn will encounter unusual conditions: a tail wind rather than a solar wind. The total pressure $(nmv^2 + p)$ may drop by a factor of 30-50 and the plasma flux (nv) by a factor of 400-600 for the hot tail plasma (cases 4 and 6). This will lead to (3) a weakening or disappearance of the bow shock and to (4) an inflation of the saturnian magnetosphere by a factor of ~ 2 . The inflation could be much stronger for the cold tail plasma (this seems, however, unrealistic). These effects could be directly observed by Voyager 2 if Saturn's immersion persisted till the third decade of August 1981.

Strong pressure gradients at the tail boundary crossing on a time scale of 1-2×10⁵ s may trigger a gigantic substorm followed by (5) a flare-up of kilometric radiation²¹⁻²³ and (6) an enhancement (by particle precipitation) of Saturn's Lya limb brightening²⁴. On the other hand, during prolonged immersion, the external magnetic field will become parallel to the plasma velocity which will lower the efficiency of magnetic field reconnection and magnetospheric dynamo.

Several observable effects are then to be expected: plasma and magnetic field effects (1), (2) (and with luck (3) and (4)) could be detected from Voyager 2; the kilometric radio wave flare (5) could be seen from Voyager 2 (and the Earth's orbit?) and the possible UV effect (6) could be detected from Voyager 2 and with some effort from the Earth's orbit25

Extended hopanes up to C_{40} in Thornton bitumen

Jürgen Rullkötter

Institute of Petroleum and Organic Geochemistry (ICH-5), Kernforschungsanlage Jülich GmbH, D-5170 Jülich 1, FRG

Paul Philip

CSIRO, Division of Fossil Fuels, Institute of Earth Resources, North Ryde, New South Wales 2113, Australia

Gas-chromatographic and mass-spectrometric investigation of the saturated hydrocarbon fraction of a distillation cut of Thornton bitumen has revealed the presence of diastereomeric pairs of side-chain-extended $17\alpha(H)$ -hopanes with carbon numbers ranging up to C40. Pentacyclic triterpanes of the hopane type are ubiquitous in sediments and related fossil fuels1. Commonly, besides the parent hydrocarbon itself, 17α (H)-hopane (C₃₀), compounds with degraded (C₂₇, C₂₉) and extended side-chains (C₃₁-C₃₅) are detected². While hopanes with 30 or fewer carbon atoms can easily be interpreted as diagenetic products of C₃₀ hopanoids, for example, hop-22(29)ene, known in several living organisms³, the extended hopanes $(C_{31}-C_{35})$ have recently been related to a C_{35} precursor, bacteriohopanetetrol, which was found to be a constituent of several microorganisms^{1,4-6}. We report here that the new C₃₆-C40 hopanes are of the same structural type as the well-known extended hopanes ranging up to C35.

The approximation $\varphi \to 0$ in equation (4) (local direction of the solar wind parallel to the Sun-Jupiter (\bigcirc -2 \downarrow) line) allows an analytical solution

For $\beta_0 = 1$ one obtains $y_s = 772 R_J$, suggesting that for very hot plasma $(\beta > 1)$ supported by more recent Voyager data²⁶, the tail should be considerably wider.

Adopted solar wind values at Saturn: $n_s v_s = 3.7 \times 10^6 \text{ cm}^{-2} \text{ s}^{-1}$, $m_s n_s v_s^2 = 2.8 \times 10^{-10} \text{ erg cm}^{-3}$, $p_s = 2n_s k T_s = 5.7 \times 10^{-13} \text{ erg cm}^{-3}$ (ref. 12).

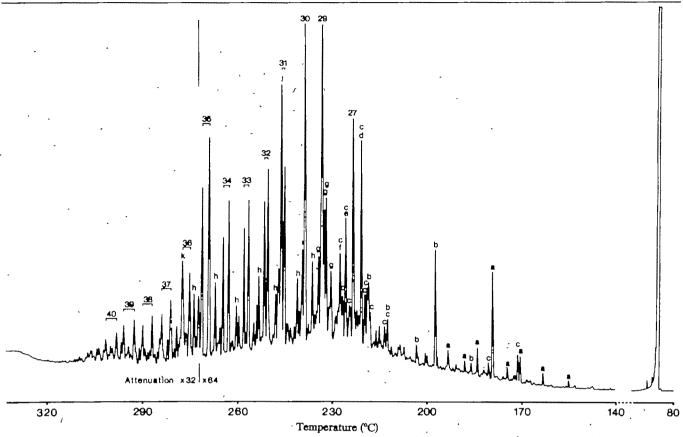

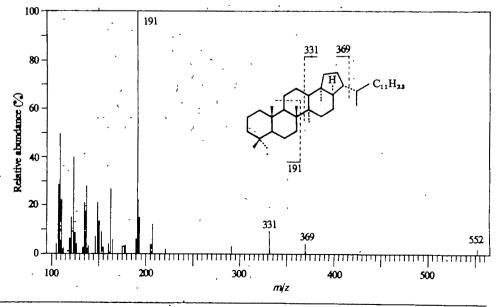

Fig. 1 Capillary column chromatogram of the saturated hydrocarbon fraction of a Thornton bitumen distillation cut. Numbers indicate $17\alpha(H)$ -hopanes (carbon atoms); a, tricyclic terpanes (C_{20} – C_{25}); b, tetracychic terpanes (C_{23} – C_{25} , C_{29}); c, steranes (C_{21} – C_{22} , C_{26} – C_{28}); d, $18\alpha(H)$ -trisnorneohopane; e, pentacyclic C_{28} -triterpane; f, C_{29} -sterane; g, 24-ethyl- $5\alpha(H)$ -cholestanes $[14\alpha(H),17\alpha(H),(20S)$ -, $14\beta(H),17\beta(H),(20S)$ -, and $14\alpha(H),17\alpha(H),(20S)$ - isomers in order of elution]; h, moretanes (C_{29} – C_{35}); i, pentacyclic C_{30} -triterpane; j, gammacerane (?); k, perhydro- β -carotene (?). A Varian 3700 gas chromatograph was used with FID-detector; 25 m×0.3 mm i.d. glass capillary column was coated with high-temperature SE 54 (Carlo Erba), injector, 300 °C; detector, 300 °C; carrier gas, helium; temperature programme, 80–330 °C (3 °C min⁻¹).

Thornton bitumen was obtained from the Thornton Quarry, just south of Chicago (Illinois). The bitumen is found in the Niagara dolomité deposited during Silurian times, and it is thought that it was formed simultaneously with the rock and thus may also be of Silurian age⁷. Rounded hillrocks of the ancient dolomite now protrude glacial clay. The rock is highly fossiliterous and contains unicellular species, and plant and animal skeletons⁷. A previous study of the saturated hydrocarbons from the bitumen by Marschner et al. revealed the absence of n-alkanes and a prominent contribution of steranes and triterpanes although no specific identifications were made.

As can be seen from the capillary column chromatogram in Fig. 1, the saturated hydrocarbon fraction of Thornton bitumen is enriched in pentacyclic triterpanes, most of which have a hopane skeleton. The most abundant compound is 17α (H)-hopane (C_{30}). 17α (H)-norhopane (C_{29}), 17α (H)-trisnorhopane (C_{27}) and 18α (H)-trisnorneohopane (C_{27}) were found as major degraded hopanes. Further tetra—and tricyclic terpanes, based on their mass spectral base peaks at m/z 191, may have structures related to hopane and may, at least in part, be derived from hopanoid precursors by degradation during diagenesis and catagenesis. Smaller amounts of steranes in Thornton bitumen

Fig. 2 Electron impact mass spectrum of the first-cluting C_{40} 17α (H)-hopane (see Fig. 1). A Varian Mat 112 S mass spectrometer was used with sonizing energy 70 eV, source temperature 260 °C, gas chromatographic conditions as given for Fig. 1.

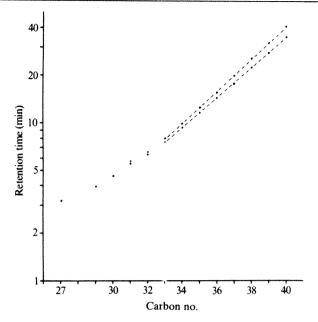

Fig. 3 Log/normal plot of retention times versus carbon number for C₂₇-C₄₀ hopanes obtained from isothermal gas chromatography at 260 °C (other conditions as given in Fig. 1). The C₃₃-C₄₀ hopanes show linear increase of log retention time, different for the C-22 diastereomers, indicating the presence of homologous series.

point to an advanced maturity level of the organic matter well within the oil window, as indicated by the dominance of 14β (H), 17β (H)-steranes⁸; this can easily be seen in Fig. 1 for the C₂₉ steranes.

Extended 17α (H)-hopanes in Thornton bitumen are pairs of C-22 diastereomers⁹ (Fig. 1). The carbon number maximum within this series at C35 either indicates a particular stability of this species or, more likely, a C₃₅ precursor for most of the C31-C35 extended hopanes as mentioned above. In contrast to hopane series reported so far, the extended hopanes in Thornton bitumen range up to C40. Diastereomeric pairs are observed as in the C₃₁-C₃₅ range together with a slight predominance of the first-eluting diastereomer (Fig. 1; the second C₃₆ isomer coelutes with a dicyclic tetraterpane, probably perhydro- β carotene). The mass spectrum of the first-eluting C_{40} hopane in Fig. 2 shows a fragmentation pattern consistent with a hopane structure with an extended side-chain. From the log/normal plot of retention times obtained at isothermal conditions against carbon number (Fig. 3), which shows a linear increase for the C₃₃-C₄₀ hopanes, the conclusion may be drawn that the sidechain extension is linear, as found for the C_{31} – C_{35} hopanes⁶, and no branching occurs.

The question now is whether the C₄₀ hopanes represent another end member in this series related to a specific precursor or whether this series extends beyond C40? This cannot be unequivocally answered from the analysis of this distillation cut. No hopanes above the C_{40} members marked in Fig. 1 could be detected in this sample, which may be due to the limiting experimental conditions (temperature) or the way the distillation cut was taken (exact temperature range unknown). If there were a C₄₀ precursor, the latter argument could explain the lower abundance of the C₄₀ hopanes relative to the C₃₆-C₃₉

As there is no precursor yet known for the C₄₀ hopanes, another mechanism for the formation of the C₃₆-C₄₀ extended hopanes is suggested. It has recently been found 10 that highly alkylated porphyrins in petroleum contain alkyl-chains up to C11. These porphyrins seem to be catagenetic products originating from porphyrin moieties bound to the kerogen matrix and released only at higher maturation levels by thermal cracking¹¹ A similar mechanism³ for the extended hopanes seems possible if one assumes that bacteriohopanetetrol (C35) is specifically

bound into the kerogen matrix during early diagenesis through a covalent carbon-carbon bond.

In addition to the extended $17\alpha(H)$ -hopanes, a series of moretanes $(17\beta(H),21\alpha(H))$ -hopanes has been tentatively identified in Thornton bitumen (Fig. 1). The series seems to include C₃₁-C₃₅ moretanes although only the C₃₁ compound in the mass spectrum clearly showed the slight dominance of the D/E-ring fragment (m/z 205) over the A/B-ring fragment (m/z 191) (ref. 12). Trace amounts of these compounds have been reported¹³ for a Toarcian shale from the Paris Basin. Unlike the $17\alpha(H)$ -hopanes, however, the extended moretanes were not detected as diastereomeric pairs (R and S at C-22) in Thornton bitumen; it seems possible that they are not separable in the given conditions2.

Support by Professor D. H. Welte is gratefully acknowledged. We also thank U. Disko and F. J. Keller for technical assistance.

Nitrous oxide cycling in Lake Vanda, Antarctica

W. F. Vincent, M. T. Downes & C. L. Vincent

Freshwater Section, Ecology Division, DSIR, PO Box 415, Taupo, New Zealand

Nitrous oxide (N2O) is a key intermediate for several steps of the aquatic nitrogen cycle. In oxygenated oceanic waters, bacterial oxidation of amino- and ammonium-N is a dominant source of N_2O (ref. 1); in regions of intense nitrification ΔN_2O values (difference between observed N2O and air-equilibrium concentration) typically rise to 40-100 nmol l⁻¹ (ref. 2). By contrast, anoxic waters are often undersaturated in N2O because of respiratory consumption by denitrifying bacteria3. We describe here an extreme accumulation of nitrous oxide (ΔN_2O of >2,000 nmol l⁻¹) in the saline bottom waters of Lake Vanda (77°35'S, 161°40'E), a warm meromictic water body in the Dry Valley region of Antarctica. From in situ experiments assaying various components of the nitrogen cycle, we conclude that this N₂O is produced by a narrow band of nitrifiers lying well above the oxycline. Nitrous oxide is lost from this zone at slow rates by diffusion, ultimately to the atmosphere above, or below to the upper anoxic zone where it is consumed by a finely stratified population of denitrifying bacteria.

Lake Vanda was sampled at a mid-lake deep-water site (maximum depth 68 m) during the austral summer of 1980–81. Holes were bored through the 3-3.5-m permanent ice-cap and 1-l samples removed with a discrete-depth water sampler. The unusual temperature and salinity profiles of Lake Vanda have been described elsewhere^{4,5}. Temperatures rise with increasing depth to a warm maximum (23.5 °C) in the region of high salinity (up to three times the conductivity of seawater) at the bottom of the lake (Table 1). Over the season of study the lake was well oxygenated to 59 m (~0.7 mmol l⁻¹ throughout, S. Nakaya, unpublished data) but anoxic at 60 m and below.

Samples were collected 21 and 27 December 1980. All depths are relative to the water table, ~0.2 m below the ice surface. Water samples for nutrient analysis were filtered immediately on collection through acid-washed glass-fibre GF/C filters and stored frozen. Analyses were performed on a Technicon AutoAnalyzer II. Lakewater controls (sample without colour reagents) were run at all depths to correct for changes in refractive index. Further control samples were run with standard nutrient additions to correct for variable recoveries at increasing salt concentrations. Nitrite was measured by automated diazotization¹⁸. Nitrate was reduced to nitrite through a cadmium wire column¹⁹ at pH 8 (ref. 20) and then analysed by standard diazotization¹⁸. NH₄ was determined by an automated phenol-hypochlorite method²¹; high values in the bottom waters of Vanda were checked manually, after 100-fold dilution, by oxidation to nitrite and diazotization²². Dissolved reactive phosphorus was by an automated molybdenum blue method²³. Particulate nitrogen was filtered on to acid washed GF/C filters and stored frozen. Material was Kjeldahl-digested and the ammonium determined colorimetrically²⁴. For gas analysis, 15-ml lakewater samples were removed from the water sampler by hypodermic syringe and injected into 30-ml Hypovials that had been sealed with neoprene²⁵ stoppers and flushed with O₂-free, N₂O-free nitrogen. These samples were immediately preserved with glutaraldehyde (2% v/v final concentration) and stored at 0°C for up to 5 weeks. Before analysis, the samples were shaken vigorously for 1 h to ensure equilibration between liquid and headspace. 1-ml subsamples of the gas were injected into a Perkin-Elmer Sigma 4 electron-capture gas chromatograph fitted with a 2-m (3 mm o.d.) stainless steel column of Chromosorb 102. The GC was operated at column temperature of 55 °C with a carrier gas (95% Ar 5% CH₄) flow of 24 ml min⁻¹. The ⁶³Ni detector was run at 375 °C with a standing current of 3.5 × 10⁻⁹ A

N₂O concentrations were well above air-equilibrium values at all depths down the oxygenated portion of the water column (Table 1). Air-equilibrium concentrations of N₂O, the saturation value for water in equilibrium with atmospheric nitrous oxide, range from 17 nmol l⁻¹ at 4.5 °C to 9 nmol l⁻¹ at 23 °C (calculated from the solubility data of Markham and Kobe⁶ and measured values for N₂O in Antarctic air⁷). Immediately beneath the ice N_2O levels were 48% above air-saturation $(\Delta N_2O=8.2~\text{nmol}~\text{l}^{-1})$. Concentrations rose steadily with increasing depth, but sharply increased below 47.5 m to a maximum at 54 m (>20,000% air-saturation; ΔN_2O >2,000 nmol l⁻¹). N₂O tensions rapidly declined below the peak, and the gas was undetectable at 62.5 m and below. The deep N₂O maximum closely followed a nitrate peak previously reported by Torii et al.8 and confirmed in the present study (Table 1). NO₃ and N₂O profiles are strongly correlated ($r^2 =$ 0.909, P > 0.001) but an accumulation of nitrite in the lower depths was displaced 1-2 m downwards relative to the other forms of oxidized nitrogen (Table 1; N2O compared with NO2 $r^2 = 0.606$).

At least four biological processes are thought to involve nitrous oxide⁹. N₂O is an intermediate in the oxidation of ammonia to nitrate by nitrifying bacteria:

$$NH_3 \rightarrow NH_2OH \rightarrow N_2O \rightarrow NO_2^- \rightarrow NO_3^-$$

It is also an intermediate in the reduction of nitrate to nitrogen gas by denitrifying bacteria:

$$NO_3^- \rightarrow NO_2^- \rightarrow NO \rightarrow N_2O \rightarrow N_2$$

Nitrous oxide has been considered a possible intermediate in assimilatory nitrate reduction by algae (reverse of the nitrifier sequence). Finally, N_2O is an alternative substrate for nitrogenase, the enzyme of N_2 fixation. This fourth process cannot be an important control on nitrous oxide levels in Lake Vanda. Acetylene reduction assays¹⁰ on lakewater samples throughout

the profile failed to demonstrate measurable nitrogenase activity at any depth.

The well-defined and coincident maxima of NO_3 and N_2O provide circumstantial evidence of a deep band of nitrifying bacteria. More conclusive evidence comes from experiments conducted in situ from 3.25 m to 57.5 m, to measure nitrypyrinsensitive CO_2 fixation (Fig. 1). Significant differences (P < 0.05) between duplicates with and without this nitrification inhibitor were recorded only from 50 to 57.5 m. Rates were highest at 52.5 m and 55 m, in the region of abundant oxidized nitrogen.

There is some evidence from marine systems^{11,12} that nitrous oxide and nitrite may accumulate as byproducts of nitrate assimilation by algae. In Lake Vanda, as in other Dry Valley lakes¹³, algal production is low throughout most of the water column but rises to a sharp maximum just above the oxycline (Fig. 1). This photosynthetic peak lies well below the zone of N₂O accumulation, and algal assimilation is therefore unlikely to be a large source of nitrous oxide.

Denitrification has been invoked² to explain accumulation of N_2O in low-oxygen regions of the sea. Denitrification in Lake Vanda was assayed by in situ acetylene blockage¹⁴ experiments at depths of 55, 58, 59, 59.5, 60, 61, 62.5 and 64 m. Significant denitrifier activity was recorded only in the upper anoxic depths of 59.5–62.5 m (Fig. 1). Nitrous oxide was very low or undetectable in this region, and therefore the upper anoxic zone must be a region of N_2O consumption rather than a net source.

A comparison of the molar ratio of N_2O to NO_3 provides a further guide to the processes controlling nitrous oxide production and loss. Lowest ratios were recorded in the region 52–56 m, the zone of peak nitrifier activity. The minimum (8.2×10^{-3}) falls within the range reported for nitrifying bacteria in culture¹⁵, although it is high relative to typical accumulation ratios in the field—Elkins et al.¹ report an average ratio of 1.4×10^{-3} mol of N_2O produced per mol of NH_4 oxidized by aquatic nitrifiers. At higher and lower depths in Vanda the ratio

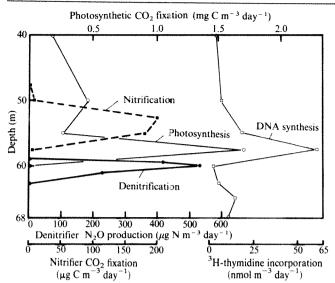

Fig. 1 Distribution of microbial activity at 40-68 m in Lake Vanda; nitrifier CO₂ fixation (■), photosynthetic CO₂ fixation (○), denitrifier N₂O production (•), 3H-thymidine uptake (□). All rates were determined by in situ incubations. Nitrifier activity (18 December 1980) was estimated by the difference between dark CO2 fixation with and without the nitrification inhibitor nitrypyrin²⁷. Samples were preincubated with inhibitor (10 mg l final concentration) for 1 h at the depth of collection, and then incubated for a further 5 h with ¹⁴C-HCO₃ (0.6 µCi ml⁻¹). Dissolved inorganic carbon was determined by IR gas analyser. Photosynthetic rates (21 December 1980) were measured by 24-h in situ ¹⁴C-HCO₃ (0.6 μCi ml⁻¹) incubations in light and dark bottles. Denitrifier activity (13 January 1981) was measured by the accumulation of nitrous oxide in samples of lakewater sealed in Hypovials and incubated at the depth of collection for 24 h with 10% acetylene1 inhibitor of nitrous oxide reductase. Samples were incubated with 3Hthymidine (20 nmol l⁻¹, 16 December 1980) to estimate microbial rates of DNA synthesis¹⁶. At the end of the 5 h incubation, samples were filtered on to 0.22 µm Millipore membranes which were washed several times with 10% trichloracetic acid and air-dried. The filters were later counted by liquid scintillation spectrometry and corrected for adsorption of label (glutaraldehyde-killed controls) and self-absorption of radiation.

of N₂O to NO₃ increased, probably reflecting the selective loss of nitrate with time by algal uptake and sedimentation. Particulate nitrogen, and by inference seasonal NO₃ removal by the plankton, is low throughout the water column (Table 1). Movement of N₂O and NO₃ by turbulent diffusion away from the peak must therefore proceed very slowly for algal uptake to affect significantly the molar ratio of the two forms of oxidized N. This ratio decreased again from 25 m towards the ice, which would be consistent with selective loss of N₂O to the atmosphere by diffusion through the ice-cap, and at the lake edge where the ice melts away each summer to produce a moat of open water 1-10 m wide.

Denitrifier activity was not detected at depths greater than 62.5 m, where N₂O and NO₃ were also absent: denitrification rates in Vanda may ultimately be limited by the rate of transfer of oxidized N to the upper anoxic zone. Ammonium substrate is relatively abundant in the region of nitrifier activity, and it is possible that phosphorus (Table 1) rather than nitrogen availability exerts an overall control on this component of the N₂O cycle. Phosphate values increased with depth towards the oxycline (Table 1), and at these lower aerobic depths total microbial activity (as estimated by ³H-thymidine incorporation into DNA¹⁶) increased to a water column maximum (Fig. 1). It remains unclear why the nitrifiers do not similarly peak in this superficially favourable environment at 57-59 m. A possible explanation is the steep ammonium gradient observed through this zone (Table 1). Nitrifying bacteria are inhibited by high levels of ammonia. Nitrobacter (nitrite oxidizer) is more sensitive than Nitrosomonas (ammonium oxidizer)¹⁷, and it is of interest that nitrite accumulates towards the bottom of the nitrification layer where ammonia becomes increasingly concentrated.

The relative importance of denitrifier and nitrifier activity for nitrous oxide accumulation in oceanic environments has caused considerable debate². In Lake Vanda, N₂O accumulated in the region of highest nitrifier activity where denitrification was

undetectable. Conversely, N₂O concentrations were greatly reduced in the region where in situ denitrification rates were maximal. In this body of water nitrification would seem to be a net source and denitrification a net sink for nitrous oxide. These different components of the N2O cycle occupy discrete bands of the stratified water column. This layered community may thereby prove to be a useful test of future models describing nitrous oxide production and loss in natural aquatic environments.

We thank Ms K. Law for technical assistance; Antarctic Division DSIR and the US Navy for logistic support; P. Johnston and the staff of Vanda station for hospitality; Drs T. Torii, S. Nakaya, E. Wada, W. Green and D. Canfield for useful discussions; Mr M. Gibbs for modifying equipment; Drs E. White, C. Howard-Williams and M. H. Timperley for critical reviews; Dr J. A. Gibb and Mr A. D. Pritchard for editorial assistance; and Ms J. Simmiss for typing each draft. Fieldwork was performed during the 1980-81 New Zealand Antarctic Research Programme.

An opiate system in the goldfish retina

Mustafa B. A. Djamgoz* & William K. Stell*

Recently, in addition to conventional neurotransmitters such as acetylcholine, dopamine, glycine and y-aminobutyric acid (GABA), putative neuroactive peptide transmitters have been localized to specific retinal amacrine cells1. In particular, opiate receptors^{2,3}, assayable enkephalin immunoreactivity⁴ enkephalin-immunoreactive neurones^{1,5} have been described in avian and mammalian retinae. However, little physiological evidence has been obtained for the involvement of neuropeptides in retinal function. Here we report that exogenous opiates affect both the release of GABA from GABAergic amacrine cells and the firing patterns of ganglion cells in the goldfish retina⁶. Our results show that the output of the retina is modulated by an opiate system whose neural organization and pharmacological properties resemble those described elsewhere in the vertebrate central nervous system.

^{*}Present addresses: Department of Pure and Applied Biology, Imperial College of Science and Technology, London SW7 2BB, UK (M.B.A.D); Department of Anatomy, University of Calgary Faculty of Medicine, 3330 Hospital Drive, NW, Calgary, Alberta, Canada T2N 1N4 (W.K.S.)

Ganglion cell unit activity was recorded from the isolated, inverted retina of goldfish using metal microelectrodes. The retina was stimulated alternately at 6-s intervals for 0.7 s with a small red light spot (1 mm diameter, 650 nm, $2\mu W\ mm^{-2}$), or annulus (1.2 mm i.d., 3.2 mm o.d.) centred on the electrode. Ganglion cell responses were classified as ON, OFF (those responding to light with an increase or decrease of firing rate, respectively), or ON-OFF (those responding to light with bursts of spikes at onset and offset of stimulus). The retina was maintained at 22 °C in moist gas (95% $O_2+5\%$ CO_2), and drugs were applied to the photoreceptor side of the retina by nebulizer; no wash-out was possible. Further details are given in Fig. 1 legend.

The synthetic opioid peptide, D-Ala²-Met⁵-enkephalinamide (DALA, Peninsula), at concentrations of 0.1-1.0 μM, increased the spontaneous and light-evoked firing of 20 ON-centre units and suppressed the post-stimulus inhibition (Fig. 1a). DALA also abolished the opponent surround response to an annulus. In contrast, spontaneous and light-evoked firing in 9 of 12 OFFcentre units, was reduced by DALA; in the other three units, this inhibition was preceded by a transient period of excitation during which the cells gave ON responses to light (not shown). ON-OFF units were less predictably affected by DALA, and their activities were modified only by concentrations greater than 1.0 µM, from which they often did not recover. Morphine (0.1-1.0 µM), like DALA, excites ON-centre cells, but the excitation is prolonged (generally irreversible) and less readily modulated by light (Fig. 1b). Naloxone (4-40 µM) inhibits the dark- and light-evoked activities of ON cells, and blocks the response to DALA or morphine when applied simultaneously (Fig. 1c). Dextrorphan (4-40 \(mu\)M) has no effect (not shown). These results indicate that the endogenous opioid transmitter may be released in the dark, although the possibility that naloxone could be blocking ON cell activity by acting at any synapse cannot be excluded.

To test whether DALA acts on ganglion cells directly or through intermediary neurones, all synaptic transmission to ganglion cells was first blocked by treating the retina with cobalt chloride (1-2 mM), then DALA was applied. In the presence of cobalt ions, both dark- and light-activated firing of ON-centre cells was suppressed, and the response to DALA was blocked (Fig. 1d). Thus, the receptors for DALA and morphine may be located on an intermediary neurone presynaptic to ganglion cells rather than on ganglion cells themselves. Note, however, that neuronal responses to enkephalins may require calcium currents⁷ that would be blocked by cobalt ions, thus a direct interaction is also possible.

Preliminary experiments indicated that enkephalinimmunoreactive neurites are scattered throughout the inner synaptic layer. As the dendrites of ON-centre ganglion cells and neurites of GABA-accumulating amacrines both ramify in the innermost sublamina of this layer⁸, the pathways of these cells were investigated further. The GABA antagonist bicuculline causes an excitation of ON-centre cells and abolition of their surround responses similar to that caused by DALA or morphine; subsequent application of DALA, however, produces no significant further increase in the firing rate (Fig. 1e). We also examined the effects of opiates on the uptake and release of GABA in the retina. We have previously shown⁸ that the GABA amacrines in goldfish can be selectively loaded by incubation with ³H-GABA in the dark, whereas type H1 cone horizontal cells are loaded by incubation in the light. Release of ³H-GABA can be induced by increasing the concentration of K⁺ in the bathing medium, and the influence of opiates and their analogues on GABA release can be tested by adding these to the medium.

Dark-adapted goldfish eye cups were cut in half. The retina was isolated from each half under dim red light and incubated at 22 °C for 15 min in the dark with 0.2 ml oxygenated Ringer's solution containing 1 μ M ³H-GABA (39.2 Ci mmol⁻¹, NEN). The retinae were then incubated separately in 10 ml of unlabelled saline for 60 min with gentle shaking and a change of solution every 10 min. The efflux of ³H-GABA from each piece

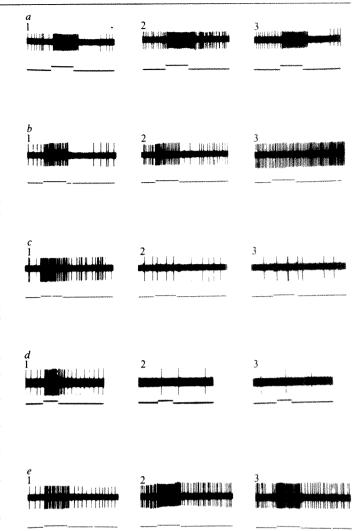

Fig. 1 Ganglion cell activity recorded extracellularly from the isolated retina of goldfish, Carassius auratus, placed in a chamber receptor side upwards and maintained and stimulated as described in the text. Concentrated stock solutions in cyprinid fish saline solution (120 mM NaCl, 2.5 mM KCl, 1.2 mM MgSO₄, 2.2 mM CaCl₂, 10 mM dextrose, 3 mM HEPES, pH 7.8) were run through an atomizer and sprayed on to the photoreceptor side of the retina; a number of solutions could be applied in turn. The dilution factor for the atomizer was estimated by spraying ³H-thymidine onto small pieces of filter paper at various dilutions and durations of application, counting in a liquid scintillation counter, and averaging the total radioactivity over a volume of retina (a circular patch 8 mm in diameter and 0.4 mm thick). Assuming that the atomized drug diffuses uniformly through the tissue, that it is neither destroyed nor taken up into retinal cells, that a steady-state concentration is achieved and that the drugs used in the physiological studies do not adhere more strongly to the stock bottles and nebulizing apparatus than ³H-thymidine, the minimum effective concentration for a readily detectable effect of DALA on ganglion cell activity was 0.1-1.0 µm. As these assumptions are certainly not valid and as each maximizes concentrations, the true minimum effective dose may be substantially lower than that estimated. The figure shows the action potentials of single ONcentre ganglion cells in the dark and in response to small, centred red light spots (square pulses below the response trace each denote $0.7 \,\mathrm{s}$). The pharmacological conditions were as follows: $a_{\rm s}$ (1) before application of DALA (control response); (2) during maximal effect of 1.0 µM DALA; (3) 5 min after application of DALA. b, (1) Control; (2) during 1.0 μM DALA; (3) during 1.0 μM morphine sulphate, after recovery from DALA. c, (1) Control; (2) after 40 µM naloxone; (3) after 40 µM naloxone + 1 µM DALA. d, (1) Control; (2) after 1 mM CoCl₂; (3) after 1 mM CoCl₂+1 μM DALA. e, (1) Control; (2) after 10 µM bisuculline methiodide; (3) after 10 µM bicuculline methiodide + 1 µM DALA. Results shown in a-e are from different ganglion cells; 1, 2, 3 in each row show responses of the same unit.

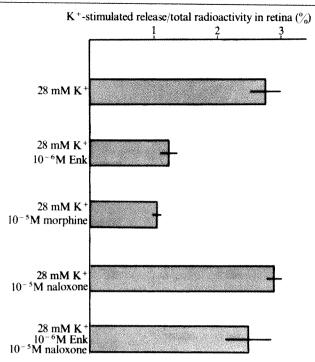

Fig. 2 The effects of enkephalin (Enk), morphine and naloxone on K⁺-stimulated release of ³H-GABA from amacrine cells of the goldfish retina. The GABAergic amacrine cells were pre-loaded by incubating the retinae in the dark for 15 min in saline containing ³H-GABA. Then the retinae were incubated with unlabelled saline for 60 min and the release of ³H-GABA into the solution was measured by scintillation counting ^{13,14} every 3 min until it became constant. Each piece of retina was then transferred to K⁺-rich Ringer's solution (28 mM K⁺) to which was added Met⁵-or Leu⁵-enkephalin (10^{-6} M), morphine (10^{-5} M) or naloxone (10^{-5} M), alone or in combination. After incubation for 6 min (2×3 min) in these solutions, each retina was again transferred to normal unlabelled saline. The percentage of ³H-GABA released from the retina by K⁺-stimulation was calculated using the following formula: K⁺-induced ³H-GABA release (d.p.m.) – ³H-GABA efflux in normal Ringer's solution (d.p.m.)/³H-GABA remaining in the retina (d.p.m.). Each value is the mean \pm s.e.m. of at least seven experiments.

of retina was measured using methods described previously 10,11 except that the K+-rich saline contained only 28 mM instead of 56 mM K⁺, and while one half was incubated in saline, the other half was incubated in saline containing enkephalin, morphine or naloxone, alone or in combination (for details see Fig. 2 legend). Using this method, we have previously shown that H-GABA accumulated by goldfish retinal cells is released in response to high external K⁺ concentrations and that this release is inhibited by 1 or 10 mM Co2+ in the medium. Figure 2 shows that enkephalin and morphine suppress the K⁺-stimulated. Ca²⁺dependent release of 3H-GABA from goldfish GABA amacrines (loaded in dark) but not from H1 cone horizontal cells (loaded in light; not shown). Both Met⁵- and Leu⁵-enkephalin have similar dose-dependent effects on GABA release, the inhibition of which ranges from 60% to 0% at 10^{-6} and 10^{-10} M enkephalin, respectively. Naloxone blocks the effect of enkephalin on GABA release from the amacrine cells but has no effect by itself in these incubation conditions. Furthermore, the suppression of K⁺-stimulated ³H-GABA release by enkephalin is not due to inhibition of the GABA uptake system, as retinae accumulate the same amount of 3H-GABA in the presence or absence of 10⁻⁵ M enkephalin, and enkephalin inhibits ³ GABA release from amacrines even in the presence of 10⁻⁴ M nipecotic acid, a specific inhibitor of GABA uptake (Chin and Lam, in preparation).

Our results show that in the inner synaptic layer of goldfish retina there are pharmacologically identifiable opioid pathways12. The pathway to ON-centre ganglion cells seems to consist of at least an intrinsic peptidergic (opioid) neurone. which may release an enkephalin, and an intrinsic GABAergic amacrine cell which is inhibited by the opioid peptide and in turn inhibits the ganglion cell. The simplest scheme for such a pathway is shown in Fig. 3. Additional elements, such as excitatory interneurones between enkephalinergic amacrine (AFNK) and GABAergic amacrine (A_{GABA}) or between A_{GABA} and the ON-centre ganglion cell, are possible. An overall effect of the presumed endogenous opioid transmitter, then, is to excite the ON-centre ganglion cells through disinhibition (opioid pathways to other ganglion cells may differ). This role of opioids in retinal ON pathways resembles their role elsewhere. For example, the immediate postsynaptic effect of enkephalins is generally inhibitory¹³, and the cells postsynaptic to enke-

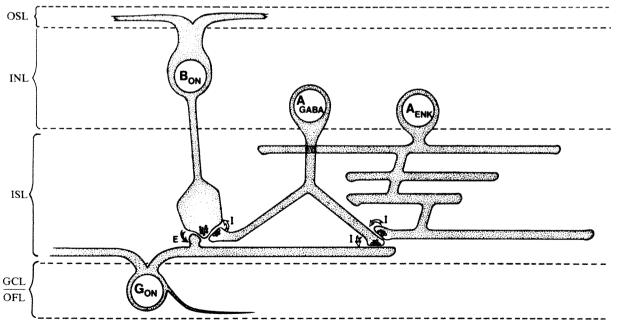

Fig. 3 The simplest probable hypothetical circuit of opioid and GABAergic neural pathways affecting ON-centre ganglion cells in the inner synaptic layer (ISL) of goldfish retina. Open arrows indicate inhibition (I); solid arrows indicate excitation (E). The presumed enkephalinergic amacrine (A_{ENK}) is inhibitory to the GABA amacrine (A_{GABA}) , which in turn is inhibitory to the depolarizing bipolar (B_{ON}) . The ON-centre ganglion cell (G_{ON}) may be inhibited by the GABA amacrine either directly or through excitatory input from the depolarizing bipolar. The nature of the synaptic input(s) to the presumed enkephalin cell are unknown. OSL, outer synaptic layer; INL, inner nuclear layer; GCL/OFL, ganglion cell/optic fibre layer.

phalinergic neurones may themselves often be inhibitory14. In specific cases described recently, exogenous opiates inhibited the activity of GABA interneurones in the hippocampus 14-16 and olfactory bulb¹⁶; the K⁺-evoked, Ca²⁺-dependent release of GABA from rat brain synaptosomes¹⁷, and the induced release in vivo of GABA from rat sensorimotor cortex18. These features are particularly clear in the goldfish retina which, because of its well-known neural organization and convenience as a natural 'brain slice', may be ideal for further testing of the organization of transmitter-specific neuronal assemblies such as these.

These results suggest interesting interpretations of the functional organization of the vertebrate retina. The precise function of amacrine cells is unknown, although they are generally supposed to have a critical role in controlling retinal output (ganglion cell responses)19. For example, in the inhibi-

tory interneurone, the GABAergic amacrine is connected and colour-coded in such a way as to impose a double colouropponent surround upon the centred ganglion cell^{20,21}. The purpose of a second inhibitory interneurone, the presumed enkephalin amacrine, in modulating the effectiveness of this surround, is unclear. However, experiments on the role of enkephalin-releasing amacrine cells in the processing of visual information may elucidate the role of enkephalinergic neurones elsewhere in the central nervous system.

Tonic in vivo inhibition of rabbit myometrial adrenergic receptors

Lawrence E. Cornett*, Alan Goldfien & James M. Roberts

University of California School of Medicine, Department of Obstetrics, Gynecology and Reproductive Sciences, Medicine and Cardiovascular Research Institute. San Francisco, California 94143, USA

With the development of radioligand binding assays for identifying hormone receptors directly, it has become evident that the number of receptors in a particular cell or tissue does not remain constant but can in fact, be regulated by a variety of agents1. Receptor concentrations decrease with exposure to homologous hormone (called densitization or down-regulation) but may be affected differently by heterologous hormones. Thus in the adrenergic contractile response of rabbit myometrium, mediated by α -adrenergic receptors², the concentration of α -adrenergic receptors is regulated by sex steroids^{3,4}. This oestrogen treatment increases the concentration of myometrial α -adrenergic receptors approximately threefold over that measured in myometrium from immature rabbits, and, furthermore, is accompanied by an increased contractile response to catecholamines5. We report here that, after 24 h in organ culture. rabbit myometrium is more sensitive to α adrenergic stimulation in vitro, and that particulate fractions prepared from cultured myometrium have a threefold increase in α -adrenergic receptors but not β -adrenergic receptors when compared with myometrium that has not been cultured. Our results suggest that the myometrium α -adrenergic receptor, in addition to being regulated by oestrogen, seems to be under tonic inhibitory control in vivo and that this control may only in part be accounted for by catecholamines.

Uteri from immature New Zealand rabbits (typically six rabbits per experiment) were pooled, the endometrium removed and myometrial strips divided equally into two groups. Myometrium in the first group was used immediately in isometric contraction studies or was homogenized and a particulate fraction prepared for binding studies, while myometrium in the second group was cultured. After 24 h in organ culture, strips were selected for isometric contraction studies or prepared for binding studies. 3H-dihydroergocryptine (DHE) was used to identify myometrial α -adrenergic receptors as described by Roberts et al.4 with several modifications (see Table 1). Binding of DHE to rabbit myometrium had been shown previously to meet the criteria for binding to the α -adrenergic receptor⁶. ³H-dihydroalprenolol (DHA) binding was found to be compatible with interaction with the β -adrenergic receptor.

Particulate fractions prepared from immature rabbit myometrium demonstrated a single class of binding site with low capacity and high affinity for DHE. After 24 h in organ culture, the concentration of DHE binding sites was significantly (P < 0.005) increased but the dissociation constant was unchanged (Table 1). The differences in the concentration of DHE binding sites in the particulate fractions prepared from cultured myometrium and myometrium that had not been cultured could not be attributed to either differences in numbers of cells as determined by DNA content⁷ of the homogenized strips (control, $5.06 \pm 0.50 \mu g$ DNA per mg wet weight; 24 h culture, 6.21 ± 0.67) or differential recoveries of protein⁸ (control, $1.6 \pm$ 0.2 mg per g wet weight; 24 h culture, 1.4 ± 0.4) or plasma membrane as determined by 5'-nucleotidase activity (control, $2.83 \pm 0.48 \mu g P_i$ per mg protein per min; 24 h culture, $2.24 \pm$ 0.41). 5'-Nucleotidase activity of the particulate fractions was determined by the method of Solymon and Trams⁹ at a protein of 0.16 ± 0.20 mg ml⁻¹ for 20 min. concentration Free inorganic phosphate was determined by the method of Chen et al. 10

DHE binding to the particulate fractions prepared from cultured myometrium retained the characteristics of α adrenergic receptor interactions. The DHE binding site was stereoselective; the (-)-steroisomer of adrenaline (K = 0.2)μM) was 20 times more potent than the (+)-stereoisomer $(K_i = 4.0 \mu M)$ in competing for DHE binding. The order of

Table 1 Dissociation constants and concentration of binding sites for DHE and DHA in rabbit myometrium

	DHE bin	C .	DHA binding (n = 4)		
	Concentration of binding sites (fmol per mg protein)	Dissociation constant (nM)	Concentration of binding sites (fmol per mg protein)	Dissociation constant (mM)	
Control 24 h organ culture	91 ± 10 $250 \pm 6*$	2.6 ± 0.3 2.9 ± 0.6	53 ± 6 46 ± 4	0.5 ± 0.1 0.3 ± 0.1	

Myometrium was cut into pieces not larger than 3×10 mm and washed in Ham's F-10 culture medium at room temperature. Myometrial strips (two to three per well) were cultured in 3 ml of serum-free Ham's F-10 culture medium with penicillin at 100 U ml^{-1} and streptomycin at $100 \ \mu g \ ml^{-1}$ in a humidified 95% air/5% CO₂ atmosphere at 37 °C. Particulate fractions were prepared as previously described except that the 10,000g centrifugation step was deleted from the protocol and dithiothreitol was omitted from the buffer used in the final pellet suspension. The DHE radioligand binding assay was used as previously described except that dithiothreitol was omitted from the assay tubes and instead ascorbic acid at a final concentration of 1.0 mM was used as an antioxidant, and the wash buffer used was $20 \ \text{mM K}_2\text{HPO}_4$, $1 \ \text{mM MgSO}_4$ at pH 8.0. Final concentrations of DHE were 1–16 nM. The DHA radioligand binding assay was identical to the DHE assay except that the temperature of the wash buffer was $4 \ \text{C}$ and the wash volume was $25 \ \text{ml}$. Final concentrations of DHA were 0.1– $16 \ \text{nM}$.

*Significantly (P < 0.005) different from control as determined by use of unpaired Student's t-test.

potency of agonist competition for binding to particulate fractions prepared from cultured myometrium—adrenaline $(K_i = 0.6 \pm 0.2 \ \mu\text{M}) \ge \text{noradrenaline} \ (K_i = 1.8 \pm 0.7 \ \mu\text{M}) \gg \text{isoprenaline} \ (K_i > 10 \ \mu\text{M})$ —is identical to the order of potency for these agonists in stimulating contraction of rabbit myometrium². Inhibitory constants (K_i) were calculated from the relationship $K_i = \text{ED}_{50}/(1 + [\text{DHE}]/K_d)$, described by Cheng and Prusoff¹¹ and are presented in Table 1 as the $\bar{X} \pm \text{s.e.m.}$ from three experiments using particulate fractions from different rabbits.

The increased concentration of DHE binding sites in myometrium after 24 h in culture was accompanied by a significant increase in sensitivity to contraction induced by noradrenaline (Fig. 1a) and methoxamine, an α -adrenergic agonist subject to neither nerve re-uptake nor metabolism by catechol-O-methyltransferase (Fig. 1b). However, there was no change in sensitivity of cultured myometrium to acetylcholine (Fig. 1c).

The leftward shifts of the dose-response curves for noradrenaline- and methoxamine-induced contraction indicate that myometrial sensitivity to adrenergic stimulation increases during organ culture. The known examples of increased sensitivity or 'supersensitivity' have been divided into two major types¹². 'Deviation' supersensitivity, or prejunctional supersensitivity¹², is characterized by changes in the amount of agonist that is available to interact with receptors. Supersensitivity of this type would arise in our system if either decreased adrenergic neuronal uptake or decreased metabolism of amines

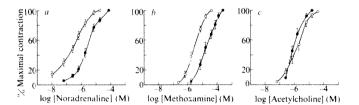

Fig. 1 Contractile response of myometrial strips that had not been cultured (●) and myometrial strips that had been cultured for 24 h (○) to cumulative doses of noradrenaline (a), methoxamine (b) and acetylcholine (c). Calculated ED₅₀ (X̄±s.e.m.) from individual experiments (n = 10) were as follows: a, ●, 2.8±0.6 μM; ○, 0.6±0.2 μM (P<0.05); b, ●, 22.2±4.0 μM; ○, 3.9±1.0 μM (P<0.05); c, ●, 3.8±1.7 μM; ○, 1.4±0.5 μM (not significant). Statistical significance was determined by use of unpaired Student's t-test. Isometric contraction studies were carried out in isolated baths maintained at 37 °C with Krebs-Ringer bicarbonate buffer (1.8 mM Ca²+, glucose at 1 mg ml⁻¹, pH 7.4) and aerated with 95% O₂/5% CO₂. Myometrial strips were suspended from a Grass FT03 strain-gauge transducer at an initial tension of 1 g for 1 h during which time the Krebs-Ringer solution was replaced at 15-min intervals. After 1 h, the tension was reduced to 0.25 g and the response recorded with a Grass physiograph. Response was calculated by integrating the area under the tracing for a standardized period of time.

was present in the cultured myometrium. As cultured myometrium was also more sensitive to methoxamine-induced contraction it is unlikely that 'deviation' supersensitivity is the underlying mechanism.

'Nondeviation' supersensitivity, or postjunctional supersensivity, as reviewed by Fleming et al.¹³, develops as a result of suppression of contact between neurotransmitter and its effector cell. Several different mechanisms have been proposed for postjunctional supersensitivity, including increased receptor concentration¹⁴. For example, in the rat depletion of neurotransmitter with reserpine leads to a leftward shift in the doseresponse curve for noradrenaline- and carbachol-stimulated potassium release of submaxillary gland slices 15 and this supersensitivity has been correlated with an increase in both α - and β -adrenergic receptor concentration¹⁶. In smooth muscle, postjunctional supersensitivity has been characterized by a nonspecific increase in sensitivity to various agonists acting on their specific receptors, and the response to changes in extracellular potassium and calcium ion concentration is altered^{14,17}. Our results show that cultured myometrium did not exhibit an increased sensitivity to acetylcholine, indicating that the observed increase in sensitivity is specific for α -adrenergically mediated contraction.

Table 2 Effect of the addition of (-)noradrenaline to the culture medium on the concentration of DHE binding sites

Treatment	DHE binding site concentration (% of control)
Control	100
8 h culture	145 ± 18
0.1 mM ascorbate	
8 h culture	101 ± 9
0.1 mM ascorbate	
1.0 μM (-)noradrenaline	

Myometrial strips were cultured as described in the text except that the culture medium was changed at 2-h intervals and after 8 h the strips were homogenized and particulate fractions prepared. In a preliminary experiment, Scatchard analysis indicated similar dissociation constants for DHE binding to particulate fractions prepared from myometrial strips cultured in the presence of either ascorbate or ascorbate and noradrenaline. Thus, it was unlikely that the particulate fractions prepared from noradrenaline-treated myometrium contained a higher concentration of noradrenaline which competed with DHE in the binding assay thereby producing an apparent decrease in DHE binding sites. To conserve tissue, the concentration of DHE binding sites was estimated by using a saturating concentration (~ 12 nM) of DHE and 10 μ M phentolamine to define nonspecific binding and was expressed as a percentage of DHE binding sites in myometrium from the same animals that had not been cultured (n=4).

* Significantly different from strips cultured for 8 h with 0.1 mM ascorbate as determined by use of paired Student's t-test.

Table 3 Effect of hexamethonium on myometrial DHE and DHA binding sites

Treatment	DHE binding sites (fmol per mg protein)	DHA binding sites (fmol per mg protein)
Control 10 mg per kg hexamethonium	80 ± 14 $159 \pm 20*$	52 ± 13 $72 \pm 5 \dagger$

Immature rabbits received five subcutaneous injections hexamethonium (10 mg per kg) dissolved in 0.9% NaCl at 6-h intervals, were killed within 1 h of the last injection and their uteri removed. Preparation of myometrial particulate fractions and binding assays, including radioligand concentrations, were performed as described in Table 1 legend. Data are reported as the $\bar{X} \pm s.e.m.$

* Significantly (P < 0.01) different from control; unpaired Student's

† Significantly (P < 0.05) different from control; unpaired Student's t-test.

The observed increase of α -adrenergic receptors in cultured myometrium suggested that tonic inhibitory influences are present in vivo. The addition of noradrenaline (1.0 µM) to the culture medium prevented the increase in α -adrenergic receptors (Table 2). However, the results from this experiment alone do not indicate a regulatory role of catecholamines in vivo. To examine this possibility further, immature rabbits were treated with hexamethonium, a ganglionic blocking agent¹⁸, resulting in a significant increase in DHE binding sites (P < 0.01) and in DHA binding sites (P < 0.05).

The finding that noradrenaline prevented the in vitro increase in the concentration of myometrial α -adrenergic receptors whereas in vivo treatment of rabbits with hexamethonium resulted in an increase in the concentration of these receptors suggests that catecholamines may tonically down-regulate the α -adrenergic receptor in vivo. However, this may not be the only process involved, because the magnitude of the increase (99%) in α -adrenergic receptors with 24 h hexamethonium treatment was less than that (260%) observed during the organ culture over the same period of time. This difference could reflect an incomplete ganglionic blockade with the dose of hexamethonium used. However, there was no further increase in myometrial DHE binding sites $(150 \pm 14 \text{ fmol per mg protein})$; n = 3) of rabbits in which the dose of hexamethonium was increased to 20 mg per kg.

Thus, our studies suggest that in addition to regulation by sex steroids³⁻⁵, the myometrial α -adrenergic receptor of the immature rabbit seems to be under inhibitory control in vivo by endogenous catecholamines and an unidentified mechanism. The techniques described for organ culture of rabbit myometrium should facilitate investigation of the cellular mechanisms involved in the control of adrenergic receptors and their relationship to physiological response in this tissue.

Monosynaptic muscarinic activation of K⁺ conductance underlies the slow inhibitory postsynaptic potential in sympathetic ganglia

John P. Horn & Jane Dodd

Department of Neurobiology, Harvard Medical School, 25 Shattuck Street, Boston, Massachusetts 02114, USA

Slow muscarinic inhibition, which lasts seconds or longer, is probably an important modulator of synaptic interactions in the central and peripheral nervous systems. Neither the cellular location of muscarinic receptors nor the ionic mechanism underlying the inhibition is well understood. In parasympathetic neurones of the cardiac ganglion in the mudpuppy, activation of muscarinic receptors leads to an inhibitory postsynaptic potential (i.p.s.p.) produced by an increase in membrane conductance to K⁺ (ref. 1). At other sites, including sympathetic ganglia, however, the situation is less clear. In the 9th and 10th paravertebral sympathetic ganglia of the bullfrog stimulation of synaptic inputs to C neurones produces a slow muscarinic i.p.s.p.2. From extracellular recordings, it was suggested3 that this slow i.p.s.p. is mediated through muscarinic excitation of an inhibitory, catecholamine-releasing interneurone. However, using similar methods, Weight et al. 4.5 reported that muscarinic receptors are located on C neurones themselves. Further controversy exists over the ionic basis of the i.p.s.p.; stimulation of an electrogenic ion pump^{6,7} and reduction of membrane Na⁺ conductance⁸ have both been proposed but remain unsubstantiated. We now present evidence, from intracellular recordings, that acetylcholine (ACh) produces a monosynaptic activation of muscarinic receptors located on sympathetic C neurones, and the i.p.s.p. is accompanied by an increase in membrane K conductance.

Sympathetic chains, including ganglia 7-10, were isolated from 4-6-inch bullfrogs (Rana catesbiana) and maintained in vitro. Spinal nerves 7 and 8, the sympathetic chain above ganglion 7 and the sciatic nerve were each fitted with suction electrodes to permit orthodromic and antidromic stimulation of ganglion cells. Cell bodies were impaled with microelectrodes made from 1.0-mm o.d. wall glass (Haer, WPI) and filled with 3 M KCl (resistances = $70-120 \text{ M}\Omega$). A bridge circuit was used to estimate membrane potential while passing current through the microelectrode. Iontophoretic pipettes were filled with 1 M ACh (resistance 100 MΩ, backing current 1-4 nA). Micropipettes were positioned under visual control with Zeiss Nomarski optics (×40 water immersion objective). The preparation was superfused with Ringer's solution composed of 115 mM NaCl, 2 mM KCl, 1.8 mM CaCl₂, 1 mM HEPES, pH 7.2. Dihydro- β -erythroidine HBr (DH β E, gift of Merck), d-tubocurarine Cl (dTC, Sigma) and atropine (Sigma) were applied by superfusion in the Ringer's.

Two classes of neurone are found in the 9th and 10th ganglia. They are identified by the origin and latency of the input producing a fast, nicotinic excitatory postsynaptic potential (e.p.s.p.). In agreement with others^{9,10}, we found that C neurones received their innervation from spinal nerves 7 and 8, whereas B neurones received theirs from higher spinal segments through the sympathetic chain. The latencies of nicotinic e.p.s.ps were 5-10 times greater in C neurones than in B neurones. In a given preparation, C neurones were generally much smaller than B neurones and cell size was used as a guide to impale C neurones preferentially. I.p.s.ps were never observed in a B neurone (see also ref. 2).

A single orthodromic shock, or a short train at 10 Hz, to an impaled C neurone in drug-free Ringer's elicited suprathreshold fast e.p.s.ps followed by a hyperpolarization of 5-25 mV, lasting 1-4 s (Fig. 1a). Superfusion with 100 nM atropine blocked the hyperpolarization which then recovered when atropine was

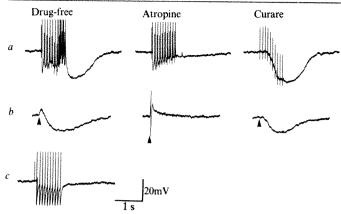

Fig. 1 Pharmacology of the i.p.s.p. a, Response of a C neurone to 10 stimuli at 10 Hz to nerves 7 and 8. b, After each synaptic trial a single iontophoretic pulse (15 nA, 5 ms) of ACh was applied (arrow). c, A train of antidromic action potentials elicited by 10 stimuli to the sciatic nerve. The tops of the action potentials in drug-free Ringer's and in 100 nM atropine have been cropped. Shock artefacts are evident in a and c. Atropine blockade was maximal by 10 min and was reversed by washing in drug-free Ringer's for 45 min. During atropine blockade, the nicotinic response to ACh became suprathreshold. After 20 min in 100 µM dTC, the fast e.p.s.p. and ACh-evoked depolarization were blocked, revealing pure hyperpolarizing Temperature = 27 °C.

washed out. The orthodromic hyperpolarization was distinctly larger than the summated afterpotential following a comparable train of antidromic action potentials (Fig. 1c). When the fast e.p.s.p. and consequent spike were blocked with either $4 \mu M D H \beta E$ or $100 \mu M d T C$, a pure, atropine-sensitive, hyperpolarizing i.p.s.p. remained. These synaptic responses were mimicked by iontophoretically applied ACh (Fig. 1b). In normal Ringer's, a single pulse of ACh produced a biphasic response consisting of an early, depolarizing phase lasting $200 \mu M c$ ms, followed by a larger, hyperpolarizing phase lasting $200 \mu M c$ selectively abolished the hyperpolarization while curariform drugs blocked the depolarization. Thus the muscarinic i.p.s.p. is present in drug-free C neurones and can be mimicked by the application of ACh.

The possibility that an interneurone is involved in the generation of the i.p.s.p. was tested by measuring the effect of blocking synaptic release on the response to iontophoretically applied ACh in a curarized preparation (Fig. 2). The iontophoretic current was adjusted so that the ACh response closely mimicked the amplitude and time course of the i.p.s.p. Then the preparation was superfused with 0.18 mM Ca²⁺, 8 mM Mg²⁺ Ringer's, which abolished the nerve-evoked slow i.p.s.p. but left the iontophoretic response unchanged. The synaptic response returned when normal Ringer's was reintroduced and both the i.p.s.p. and the ACh responses were then blocked completely with atropine. This demonstrates that the muscarinic action of ACh is independent of Ca²⁺-sensitive release and is probably a direct effect on C cells.

The mechanism underlying the i.p.s.p. was examined by varying the membrane potential. In 20 cells, in which 10 stimuli at 10 Hz elicited an average i.p.s.p. of $12\pm1.8\,\mathrm{mV}$ (s.e.m.) at resting potential $-51\pm1.5\,\mathrm{mV}$ (s.e.m.), polarizing current produced the effects illustrated in Fig. 3a. Depolarizing current reduced the amplitude and duration of the i.p.s.p. With progressive hyperpolarization, i.p.s.p. amplitude increased to a peak value, then became smaller and reversed. The i.p.s.p. reversed at a membrane potential near that at which the antidromic action potential afterpotential reverses. From recordings made with a balanced bridge circuit we estimated that the i.p.s.p. reverses at $-100\pm4.2\,\mathrm{mV}$ (s.e.m.), n=4 and the spike afterpotential reverses at $-88\pm2.4\,\mathrm{mV}$ (s.e.m.), n=5 (for example Fig. 3c,d).

Interpretation of the voltage sensitivity of the i.p.s.p. requires information about the current-voltage (I-V) relationship of C

cells. Figure 3b is an I-V plot obtained by passing a slow current ramp through a balanced electrode. It is representative of data from five cells in which the average slope resistance increased sharply from $93\pm14~\mathrm{M}\Omega$ (s.e.m.) to $380\pm59~\mathrm{M}\Omega$ (s.e.m.) during hyperpolarization from rest. Over the linear, high-resistance range of the I-V curve, i.p.s.p. amplitude was a linear function of membrane potential and underwent reversal, suggesting a synaptically activated increase in membrane conductance. The curved portion of the I-V curve coincided with the range in which i.p.s.p. amplitude and spike afterpotential amplitude deviated from a linear dependence on membrane potential (compare Fig. 3b with c and d). In other words, both the i.p.s.p. and the afterpotential appeared to be shunted by a decrease in membrane input resistance at depolarized potentials.

The muscarinic conductance change was also investigated by passing 0.5-s current pulses across the membrane before and during the i.p.s.p. (not shown). As expected, there was always a decrease in membrane resistance during the i.p.s.p. over the linear, high-resistance part of the I-V relationship. In the region of transition from low- to high-input resistance we sometimes observed a resistance increase during the i.p.s.p. (see also refs 4, 8). However, this increase was consistently smaller than that produced by simply hyperpolarizing the membrane with injected current in the absence of an i.p.s.p. Thus despite the apparent decrease, the i.p.s.p. was always accompanied by an increase in membrane conductance. In three cells the conductance increase during the i.p.s.p. ranged from 1.6 to 3.9 nS. These estimates were made over the linear portion of the I-V plot and represent approximately a doubling of resting membrane conductance $(1/380 \text{ M}\Omega = 2.6 \text{ nS})$.

The preceding experiments imply that K^+ and/or $C1^-$ carry synaptic current. Such possibilities are usually distinguished by altering ion concentration gradients. The fact that use of KCl-filled microelectrodes had no discernible effect on the i.p.s.p. reversal potential suggests that $C1^-$ is not involved. In contrast, when extracellular K^+ was increased from 2 to 10 mM, the reversal potential shifted to a substantially depolarized value (Fig. 4), indicating that K^+ carries synaptic current.

Taken together, these experiments indicate a similarity between the muscarinic i.p.s.ps of bullfrog sympathetic neurones and mudpuppy parasympathetic neurones: each involves a monosynaptic process dominated by an increase in K⁺ conductance. Furthermore, the inhibitory nature of this mechanism has been demonstrated. In some conditions (Fig. 3a, 0 pA and +40 pA) C neurones fired repetitively in response to a single antidromic shock and the i.p.s.p. blocked this firing. The

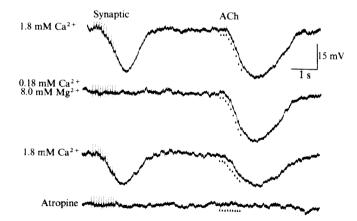

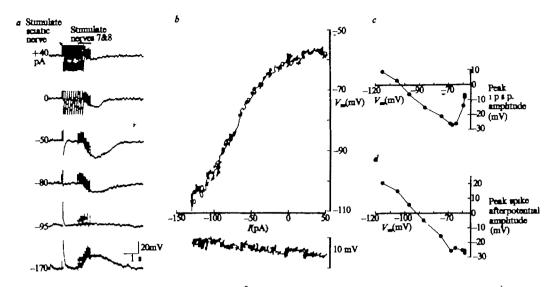

Fig. 2 Blocking synaptic release does not alter the muscarinic action of ACh on a C neurone. In normal Ringer's, containing $100 \,\mu\text{M}$ dTC, the synaptic response (10 stimuli at 10 Hz to nerves 7 and 8) was mimicked by iontophoretically applied ACh (nine pulses of 20 nA, 4 ms, marked by arrows). After 10 min in 0.18 mM Ca²⁺, 8 mM Mg²⁺ Ringer's, the synaptic response was selectively blocked. After 20 min of washing in normal Ringer's, the synaptic response returned. Both the synaptic and the AChevoked responses were completely blocked by 100 nM atropine. Temperature = 22 °C.

Fig. 3 Voltage sensitivity of the slow i p.s.p. spike afterpotential and input registance of a C neurone bathed in 100 µM dTC. a, Intracellular recording of responses to a angle antidromic shock followed by a short orthodromic train at different lovols polarizing current (left). At 0pA and +40pA the antidromic shock produced repetitive firing which was stopped by the i.p.s.p. (Control trials showed that the i.p.s.p magnitude was unaffected by the repetitive firing.) b. Top, after balancing the bridge circuit of the microelectrode amphifier, a slow current ramp (such that $dV/dt < 4 \text{ mV s}^{-1}$) was passed into the cell

and used to construct an I-V curve by playing the data into an x-y plotter. Bottom, the electrode was then withdrawn from the cell and the same current ramp was passed through the electrode alone. Membrane potentials were estimated in the range over which the unbalanced electrode resistance was <10% of the total measured intracellularly. The unbalanced electrode resistance was -20 MΩ. Subtracting this from the top plot gives alope resistances of 135 MΩ at 0 pA and 505 MΩ. at -100 pA c, A graph of peak: p.a.p. amplitude versus membrane potential (Vm). d, Graph of peak action afterpotential versus membrane potential Note that the bend in the cell's F-V relationship coincides with the potential at which the relationships in c and d deviate from linearity. Temperature = 22 °C.

powerful influence of the i.p.s.p. on membrane properties suggests how monosynaptic inhibition might contribute to the integrative function of autonomic neurones.

Recognition of H-2 domains by cytotoxic T lymphocytes

C. Weyand, G. J. Hämmerling* & J. Goronzy

Institut für Immunologie und Genetik, Deutsches Krebsforschungszentrum, Heidelberg, 6900 Heidelberg. Im Neuenheimer Feld 280, FRG

The polymorphic major histocompatibility antigens (H-2) have a crucial role in the activation of antigen-specific T lymphocytes. Thus, H-2 antigens are not only recognized by allogeneic lymphocytes leading to generation of cytotoxic T lymphocytes (CTLs), but it has also been demonstrated that in syngeneic systems most T cells are only able to recognize foreign antigens in conjunction with their own MHC (major histocompatibility complex) antigens. This phenomenon, termed H-2 restriction¹ may be the key to our understanding of the biological function of MHC antigens. It is not clear whether recognition by T cells of H-2 on a molecular level is confined to particular domains on the H-2 molecule, nor whether the same polymorphic H-2 sites, which are characterized by antibodies, are recognized by allogeneic as well as by H-2-restricted syngeneic CILs. Previous findings² indicate the existence of at least two major poly-morphic domains on the H–2K^k molecule as defined by antibodies. Here we show the existence of CTLs with specifity for these polymorphic domains, and the preferential recognition of a particular domain by both alloreactive as well as H-2-restricted CTLs.

Recent competitive antibody-binding studies using six monoclonal antibodies against different determinants on the

^{*} To whom correspondence should be addressed

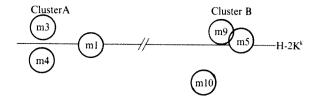

Fig. 1 Antigenic determinants on the H-2K^k molecule are concentrated in two clusters. This schematic diagram of the spatial relationship of H-2K^k determinants was obtained by antibody competition studies in which the binding of six different radiolabelled monoclonal antibodies to H-2K^k-bearing cells was competed by addition of various cold antibodies in all possible permutations. The 50% inhibition values have been used as a very rough measure of the relative distance between determinants on the H-2K^k molecule. Antibodies within one cluster cross-block each other to varying degrees but do not interfere with binding to the other cluster, as described in more detail elsewhere². Biochemical evidence indicates that all six determinants are located on the same molecule.

H-2Kk molecule³ have provided information on the steric relationship of individual determinants². The six H-2K^k determinants defined by monoclonal antibodies are concentrated on the H-2K^k molecule in two spatially separated polymorphic domains, clusters A and B, which are shown schematically in Fig. 1. We have used these monoclonal antibodies to block the target antigen for allogeneic as well as H-2-restricted CTLs to assess which H-2 sites are target epitopes for CTLs. H-2Kkspecific CTLs were produced in vitro by activation of DBA/2 splenocytes with irradiated A/J stimulator cells. Figure 2 shows the ability of different concentrations of monoclonal anti-H-2K^k antibodies to block target cell lysis. None of the monoclonal antibodies completely inhibited cytolysis, whereas a mixture of these plus a polyvalent anti-H-2Kk alloantiserum almost completely blocked target cell lysis. These findings indicate that single monoclonal antibody bound to a particular determinant on the H-2Kk molecule prevents the interaction of only some, but not all, CTL clones with the target molecule, suggesting the existence of different CTL clones with specificity for distinct H-2 determinants. This conclusion has been supported by target inhibition of alloreactive as well as H-2-restricted CTL clones generated in a limiting dilution system which showed that individual monoclonal antibodies block only 10-50% of CTL clones (our unpublished data).

Figure 2 clearly shows that the monoclonal antibodies fall into two distinct groups which differ with regard to their inhibitory capacity. Antibodies belonging to cluster A (see Fig. 2a, centre panel) reduce 51 Cr release from 80% to \sim 40% of the plateau level while those of cluster B reduce cytolysis to \sim 20%. The same difference is observed when the monoclonal antibodies are used at maximal inhibitory concentration (1:50 or 1:100 dilution), the ratio of killer cells to targets being varied (see Fig. 2b). Again monoclonal antibodies to cluster B are much more efficient in target inhibition, suggesting that more CTL clones are reactive against determinants belonging to cluster B than against those belonging to cluster A.

Next, we analysed an H-2-restricted CTL system in which CTLs from H-2^k mice recognize the hapten trinitrophenyl (TNP) linked to the H-2K^k molecule⁴. CBA splenocytes were sensitized in vitro with TNP-conjugated CBA spleen cells and cytolytic activity was determined after 6 days of culture on TNP-conjugated H-2^k target cells. Control experiments established that the TNP-specific CTLs were predominantly restricted by the K end (data not shown). Inhibition of the TNP-specific CTLs by anti-K^k antibodies showed again that each individual antibody blocks only a fraction of the CTL effector population while a mixture of monoclonal antibodies or a polyvalent antiserum against K^k almost completely prevents lysis (see Fig. 3). These findings indicate that CTLs can recognize TNP in conjunction with different H-2 determinants, or in other

words, that one $H-2K^k$ molecule carries more than one restriction site. As was also observed for allogeneic anti- K^k CTLs (Fig. 2), it was found for the TNP system that antibodies to cluster B were much more effective in preventing target cell lysis than antibodies to cluster A. The same conclusion was reached when the antibody concentration was constant at maximal inhibitory concentration (1:50-1:100 dilution) and the killer cells titrated (data not shown).

Calculation of lytic units provides an estimate of the relative number of CTLs in a population⁵. These data (see Table 1) show that in the presence of monoclonal antibodies to cluster B, on average three times fewer lytic units are measured than in the presence of monoclonal antibodies to cluster A. Taken together, these data suggest that about three times as many alloreactive and self-restricted CTLs are present which react with determinants of cluster B.

Target inhibition by monoclonal antibodies has also been described by others^{6,7} but our report provides additional information on the correlation of CTL specificity with the steric arrangement of H-2 determinants. The data show that both alloreactive as well as TNP-specific H-2-restricted populations are heterogeneous with regard to which H-2 epitopes on a given molecule are recognized, and that both CTL populations show preference for a particular domain on the H-2K^k molecule which is characterized by antibodies to cluster B. It is not clear from our results whether CTLs recognize exactly the same determinants as monoclonal antibodies or whether the latter block spatially related determinants only by steric hindrance. Another possibility is that monoclonal antibodies induce con-

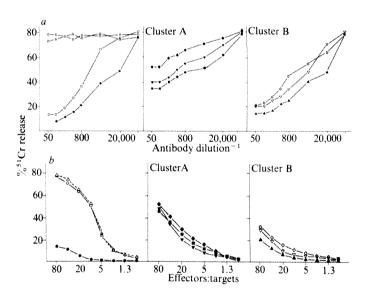

Fig. 2 Target inhibition of H-2Kk-specific alloreactive CTLs by monoclonal anti-H-2K antibodies. 10×10^6 DBA/2 (d/d) spleen cells were stimulated with 12×10^6 A/J (k/d) irradiated spleen cells as described elsewhere. After 5 days, CTL activity was measured against 51 Cr-labelled L929 (H-2k) target cells for 4 h in the presence of anti-Kk antibodies in a total volume of 200 µl using methods described previously⁶. These CTLs were shown to be specific for K^k (results not shown). In some experiments B10.D2 responders and B10.A stimulators were used. The figure shows a typical experiment which was repeated several times with the same results. a, Effect of different concentrations of monoclonal antibodies ascites on cytolysis at an effector to target ratio of 50:1. Fig. 3 Target inhibition of TNP-specific $H-2K^k$ -restricted CTLs from CBA $(H-2^k)$ mice by monoclonal anti- K^k antibody. TNPspecific CTLs were produced in vitro by activation of CBA splenocytes against TNP-conjugated CBA spleen as described elsewhere⁴. CTL activity was measured at an effector to target ratio of 50:1 against TNP-conjugated ⁵¹Cr-labelled L929 (H-2^k) target cells in the presence of various concentrations of blocking antibodies. By using different targets as well as cold target inhibition it was established that most CTLs were restricted by Kk. From other studies it is known that the antibodies used here mediate their blocking effect by inhibition of the target determinant and not when they are directed against the effector cells⁶. Symbols are the same as for Fig. 2. Left frame: ○, medium control; △, control ascites 13/18; , BALB/c anti-A/J alloantiserum; , mixture of six monoclonal anti-K^k antibodies. formational changes at distal parts of the H-2 molecule which influence the interaction with CTLs. However, we consider it more likely that both CTLs and antibodies recognize basically the same polymorphic domains. The different blocking capacity of monoclonal antibodies to clusters A and B is not likely to be due to distinct physical properties of the monoclonal antibodies because those used here have similar affinities (ref. 8 and H. Lemke, personal communication) and belong to similar immunoglobulin classes (IgG2a and IgG2b, respectively). An exception is H145-45/2, which after recent re-evaluation was found to be IgM (unpublished data); the fact that it is pentameric may explain its very strong inhibitory capacity.

A possible explanation for the striking preference of alloreactive and H-2-restricted CTLs for cluster B is that both H-2^d (DBA/2 or B10.D2) and H-2^k mice use a similar or related pool of T-cell receptors for recognition of the Kk molecule, whether an alloantigen (in the case of DBA/2) or a self antigen (in the case of CBA) is recognized. Such a hypothesis would be compatible with dual recognition models, one binding site being for TNP and the other for H-2 determinants. Arguments in favour of single recognition models assume that neodeterminants formed by TNP modification of either H-2 or other surface components are predominantly located in the

Lytic units (LU) were calculated according to Cerottini et al.5 on the basis of CTL effector titrations as shown in Fig. 2b for alloreactive CTLs. The corresponding titration curves for TNP-specific CTLs are not shown. One lytic unit is defined as the number of effector cells required to lyse 50% of the target cells.

direct vicinity of polymorphic H-2 domains. Target inhibition of restricted CTLs by anti-H-2 would then be caused by steric hindrance. Note that preference of different CTL populations for the same cluster could be merely coincidental as it is possible that an H-2 molecule carries only few regions which, for steric reasons, are accessible to T cells. Further analysis of Kk-restricted CTL systems will clarify this question.

Light chain isotypes selectively associate with heavy chain idiotypes in T-dependent and T-independent dextran-specific precursors

Ronald E. Ward*, John F. Kearney† & Heinz Köhler*

In murine immunoglobulins, the κ chain is the major light chain isotype, as exemplified by the small amount of λ immunoglobulins present in normal sera, the rare occurrence of λ plasmacytomas and the preponderance of κ light chains in induced antibodies. Notable exceptions to this are the response to $\alpha(1\rightarrow 3)$ dextran¹ in BALB/c mice and the heteroclytic antibodies raised against the nitrophenol hapten in C57BL/6 mice². In the former response, the expression of idiotypes in the hypervariable regions of the heavy chain³ is characteristically restricted. We have now analysed the B-cell precursors for the $\alpha(1 \rightarrow 3)$ linkage-specific response induced by T-dependent and T-independent dextran antigens with respect to light chain isotype and heavy chain idiotype expression. Our findings clearly demonstrate that the two forms of dextran antigen trigger different B-cell precursor subpopulations. Furthermore, each individual animal appears to possess a different repertoire of idiotype-committed precursors. This contrasts with the response of BALB/c mice to phosphorylcholine (PC) where most anti-PC antibodies and precursors respond with the dominant expression of the T15 idiotype family, regardless of whether T-dependent or T-independent PC antigens are used*.

BALB/c mice immunized with the T-independent antigen dextran B1355s respond with the expression of unique idiotypes (IdI) J558 and M104E, and a cross-reacting IdX idiotype⁵. Schilling and co-workers⁶ have shown that the unique IdI specificities are generated during the V-D-J joining process of heavy chain genes. While the expression of λ chains in the T-independent anti-dextran BALB/c response is consistently >90%, the amount of J558 and M104E IdI idiotypes varies between individual animals^{7,8}. This finding led us to speculate that the variable expression of heavy chain idiotypes might be caused by individually different, idiotype-specific regulation of B-cell precursors. Alternatively, during the development of the dextran-specific repertoire individually different exposures to environmental antigens could influence precursor maturation. According to the latter hypothesis, serum expression of light

‡ The statistical probability that the two given idiotypes will be co-expressed, based on the relative frequency of each idiotype alone.

chain isotypes and heavy chain idiotypes should directly reflect the differently established primary B-cell repertoire in individual animals.

Spleen cells from normal BALB/c mice were transferred in limiting cell numbers to 1,400 rad-irradiated normal or haemocyanin-primed syngeneic recipients. Twenty hours later, splenic fragment cultures were prepared according to the technique of Klinman⁹, modified for the analysis of T-dependent and T-independent B-cell precursors⁴. Fragment cultures were immunized with either dextran B1355s or dextran coupled to haemocyanin as described previously¹⁰. Culture supernatants were collected at 3-day intervals beginning on day 6 of culture and assayed for light chain isotype, heavy chain idiotypes and total anti-dextran antibody production, using enzyme-linked assays or radioimmunoassays (RIPs). Monoclonal antibodies were used to detect the cross-reacting IdX idiotype and the J558 and M104E IdI idiotypes¹¹. Figure 1 shows the percentage of heavy chain idiotypes and light chain isotypes calculated from data on 182 T-dependent and 129 T-independent dextran-

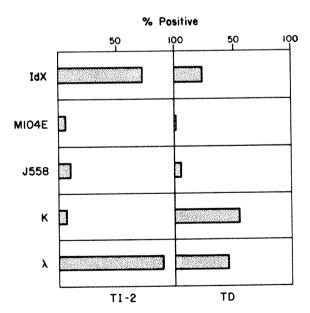

Fig. 1 The per cent positive dextran-specific precursors is plotted against the heavy chain isotype and the light chain idiotypes. Splenic fragments were immunized with either dextran B1355s (T-independent (TI)-2) or dextran-haemocyanin (T-dependent, TD). Supernatants were collected every 3-4 days and analysed for total anti-dextran antibodies, light chain isotype and heavy chain idiotype by RIA and enzyme-linked immunosorbent assay using monoclonal anti-J558 EB3-7-2. γ1k, raised in A/J mice, monoclonal anti-M104E SJL 18-1, μk, raised in SJL mice, and monoclonal anti-IdX CD3-2, γ1λ, raised in A/J mice.

specific precursors. Precursor clones responding to the $\alpha(1 \rightarrow 6)$ linkage, present in dextran B1355s, were excluded by testing for inhibition with dextran B512 $[\alpha(1\rightarrow 6)]$ in the anti-dextran RIA¹⁰. The data show that the IdI-producing clones in the T-dependent and T-independent anti-dextran precursors are infrequent; most T-independent precursors express the crossreacting IdX heavy chain idiotope while T-dependent precursors express the IdX idiotype in <25% of dextran-specific clones. Furthermore, T-dependent precursors express the k chain more frequently than do T-independent precursors. The ability of T-dependent precursors to express both λ and κ light chains could explain why the frequency of dextran precursors responding to the T-dependent antigen is higher than that of T-independent precursors¹⁰. Although the relative fraction of IdX precursors is smaller in the T-dependent than in the Tindependent response, the absolute number of IdX precursors does not appear to differ much for T-dependent and Tindependent dextran antigens. Thus the selection of heavy and light chains is dictated by the type of dextran antigen.

The question of whether heavy chain idiotypes can freely combine with λ and κ light chains or whether their association is restricted cannot be answered from the collective precursor analysis data shown in Fig. 1. Therefore, individual clones were grouped together according to their co-expression of light chain isotypes with heavy chain idiotypes. The relative frequencies of clones co-expressing a certain light chain with a certain idiotype were calculated from the total number of T-independent and T-dependent dextran-specific clones. The data are shown in Table 1. The most frequent combination is the co-expression of λ and IdX in T-independent and T-dependent precursors (group 1). No precursors were found which co-expressed κ and any of the heavy chain idiotypes. A small number of Tindependent and T-dependent precursors were positive for J558 IdI and IdX; none was positive for M104E IdI and IdX. These data demonstrate that the J558-M104E IdI idiotype site is different from the IdX site, in agreement with the assignment of IdI and IdX sites in hybridoma anti-dextran antibodies made by Schilling et al.6. The failure to find M104E IdI- and IdX-positive clones is not surprising considering the rare occurrence of M104E IdI precursors. However, the failure to detect known heavy chain idiotypes, that is, M104E, J558 and IdX, in precursors expressing the k light chain is striking.

It is important for the evaluation of fragment cultures secreting more than one idiotypic antibody to determine the probability of two different clones being present in one fragment. The expected frequency of clonal precursor doublets was calculated from the number of single idiotype-secreting cultures. The finding of a clone expressing J558 and M104E is unexpected, and unlikely to result from the presence of two different clones present in a single fragment culture as the likelihood of a clonal doublet at the given experimental limiting cell dose is >1 in 1,000 (see group 9 in Table 1; 0.1 in 129 T-independent clones).

[†] Splenic fragments were immunized with either dextran B1355s (T-independent-2) or dextran-haemocyanin (T-dependent). Supernatants were collected every 3-4 days and analysed for total anti-dextran antibodies. Positive wells were selected and analysed for the co-expression of the appropriate light chain isotype and heavy chain idiotype. The numbers in parentheses represent the number of clones which co-express the isotype and idiotype out of the total number of positives examined.

Normal or haemocyanin-primed BALB/c mice were irradiated with 1,400 rad and used as recipients of individual adult syngeneic cells. Splenic fragments were immunized with dextran B1355s or dextran-haemocyanin and supernatants were collected every 3-4 days and analysed for total anti-dextran antibodies. Dextran-specific precursors were analysed for J558 IdI, M104E IdI and IdX idiotype as described in Fig. 1 legend.

It would be attractive to assume for the double IdI-positive clone that both chromosomes have made a productive but different DNA rearrangement resulting in two active genes producing J558 and M104E messages.

We have previously^{7,8} observed variation of the amount of heavy chain IdI idiotypes in individual mice immunized with dextran B1355s. For example, the amount of J558 IdI in four randomly selected BALB/c mice 7 days after immunization with dextran B1355s varied from 7 to 53% of the total antidextran reponse. To determine whether this individually different idiotype expression is the result of idiotype-specific regulation, induced by antigenic stimulation, or is predetermined by the number of idiotype-committed precursors, precursor analysis of individual BALB/c mice was performed. Table 2 shows that individual mice indeed express the IdI idiotypes in significantly different amounts for T-dependent and T-independent responses. The relative J558 IdI frequency for T-independent precursors in individual animals was 4-50% and for T-dependent J558 IdI 3-23% (see Table 2). The overall (averaged) expression of J558- and M104E-positive precursors, as well as the number of T-dependent and T-independent responding precursors, is in good agreement with the data from analysis on precursors from pooled cell donors.

The present findings lead to three conclusions important for the understanding of mechanisms controlling idiotype expression. (1) Certain heavy chain idiotypes seem to depend on the combination with one kind of light chain. (2) Different antigenic forms of the same antigenic determinant can trigger different precursors: T-dependent dextran antigen triggers significantly more κ precursors than the T-independent dextran B1355s. Conceivably, T cells, which participate in the T-dependent response, help to recruit κ chain B-cell precursors. (3) Individual mice possess variable frequencies of precursors expressing different idiotypic specificities. Although the individually variable expression of idiotypes after immunization^{7,8} has not been formally linked to variable idiotype precursor frequencies, we could infer that individual idiotype expression stems directly from the presence of variable precursor compositions. Accordingly, individual variation of precursor frequencies must be generated during the maturation of the B-cell repertoire in the fetal-neonatal period¹². Idiotype-specific factors might be important in controlling the development of B-cell repertoires¹³. In addition, isotypic network interactions control the expression of idiotypes in the adult animal during primary or established immune responses 14-17. Comparison of the immature with the mature idiotype repertoire will help to define the role of regulatory mechanisms in establishing clonal immune profiles18

Independent control of immunoglobulin heavy and light chain expression in a murine pre-B-cell line

Christopher J. Paige*, Paul W. Kincade† & Peter Ralph†

- † Basal Institute for Immunology, Grenzacherstrasse 487, CH-4005 Basal, Switzerland
- † Laboratory of Haematopoietic Development, Sloan-Kettering Institute, Rye, New York 10580, USA

B lymphocytes differentiate from multipotential stem cells by an unknown number of intermediate stages. Although the earliest stages of this sequence remain obscure, cells, which appear to be intermediate in this process, have been described1-7. Large, proliferating, rapidly sedimenting cells which synthesize immunoglobulin chains that can be easily detected in the cytoplasm (clg) but are either absent or less stable on the cell surface (sIg) have been found in both fetal liver and adult bone marrow. Smaller clg⁺ slg⁻ cells have also been described^{2,5,7}. These cells are designated pre-B cells and may comprise a functionally heterogeneous group of progenitors. Several cell lines, which share many properties with these postulated precursors, have been useful in establishing an asynchronous onset of immunoglobulin expression characterized by the appearance of μ heavy chains in the absence of light chain expression 10-12. We confirm here that the mitogen-responsive pre-B-like cell line, 70Z/3, in normal growth conditions, only expresses heavy chain, although it has a fully rearranged light chain gene 13. 70Z/3 cells can also display the μ chain on the cell surface in the absence of light chain induction, most notably after exposure to dextran sulphate.

The 70Z/3 cell line synthesizes immunoglobulin detectable only intracellularly, but on exposure to lipopolysaccharide (LPS) the cIg⁺ sIg⁻ cell type rapidly acquires sIg⁵. Concomitant with the induction of sIg is the appearance of κ light chains¹⁴. There is, however, no evidence for secretion⁹. The increase in κ chain synthesis is related to induction of κ mRNA¹⁵.

The initial hypothesis, that light chain synthesis is causally related to surface acquisition of immunoglobulin, is not necessarily the case. This was demonstrated using a second B-cell mitogen, dextran sulphate (DxS). As shown in Fig. 1, exposure to LPS led to the acquisition of both μ and κ , whereas exposure to DxS resulted in a similar level of surface μ expression without expression of κ chains. Furthermore, the kinetics of μ expression differ after exposure to these two mitogens. Figure 2 shows that the detection of μ after DxS stimulation preceded that of both the μ and κ induced after LPS stimulation although ultimately similar levels were achieved. DxS does not, however, inhibit κ induction by LPS (data not shown).

Exposure to these mitogens neither altered the rate of proliferation, nor caused cell death and, although the kinetics of induction were variable, in most experiments > 90% of the cells were sIg⁺ within 24 h (two cell cycles). It thus seems unlikely that different subpopulations of cells account for these results. Furthermore, most clones of 70Z/3 cells also respond to both DxS and LPS (see below), and the relative sensitivity of the reagents used to detect μ and κ chains was found to be similar.

We observed that whereas the μ and κ found on the membrane of LPS-stimulated cells was distributed over most of the cell surface, the μ chains detected on DxS-stimulated cells were usually found in tight caps. These tight caps were partially inhibited (95% capped reduced to 50%) by prior treatment with

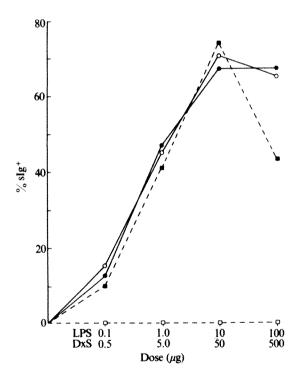

Fig. 1 Increase in surface immunoglobulin expression in 70Z/3 cells exposed to various concentrations of LPS (Salmonella typhosa WO 901, Difco) or DxS (Pharmacia) for 36 h. Surface expression of either μ or κ chains was assessed using affinity-purified, rhodamine-conjugated goat antibodies specific for either μ or κ which were prepared and used as previously described. LPS, μ ; \bigcirc , LPS, κ ; \bigcirc , DxS, μ ; \bigcirc , DxS, κ ; 70Z/3 cells were grown in RPMI-1640 containing 10% FCS (Associated Biomedic Systems) and supplemented with 5 mM glutamate, 10^5 U⁻¹ 1 penicillin, 0.1 g⁻¹1 steptomycin and 5×10^{-5} M 2-mercaptoethanol. Cell cultures were initiated at 2.5×10^5 mi⁻¹ grown in 25-cm³ tissue culture flasks (Corning) and kept at 37 °C in a humid atmosphere containing 7% CO₂.

cytochalasin B (30 min, 37 °C, 10 μg ml⁻¹) but not by staining in the presence of 1% NaN₃.

Possible explanations for the different cell surface distribution of μ chains after exposure to LPS or DxS include that: (1) the μ appearing after DxS stimulation differs from the μ found after LPS stimulation; (2) the presence of κ chains, although not necessary for the appearance of μ on the surface, is required for the stability of the sIg; or (3) a cell-surface alteration unrelated to immunoglobulin molecules may be responsible. It is also possible that the uninduced cells possess a small but undetectable amount of surface μ which undergoes a conformational change on exposure to DxS, leading to enhanced expression. Biochemical evaluation of the DxS- and LPS- induced μ is underway and may resolve these issues.

Additional differences in the responses to these two mitogens was found by analysing clones of 70Z/3 obtained by growth in soft agar. Although 19 of these clones (70Z/3.2-70Ž/3.20) had similar characteristics to the parent line and could respond to both LPS and DxS, one clone, 70Z/3.1, lost the ability to respond to LPS, although retaining DxS responsiveness (Table 1). This clone was refractory to even 100 times the concentration of LPS normally used. Furthermore, the parent line and LPS-responsive clones, if grown in the presence of serum-free medium, failed to respond to LPS although the DxS response was normal (Table 1). After an initial period of adaptation, growth in this medium was similar to growth in serumcontaining medium and LPS responsiveness was restored by addition of 2% fetal calf serum (FCS). This may indicate that serum contains components which condition the cells for responsiveness to LPS. Previously we found that different batches of either FCS or newborn serum themselves could cause background levels of sIg+ cells to vary from 1 to 99% (ref. 9, and unpublished data). It should be noted that in almost all these cases of elevated background expression of μ , light chains were not detectable. Thus, DxS is not obligatory for the detection of the 'u only' surface phenotype. Furthermore, recent data suggest that the surface μ is indeed membrane μ and not secretory. First, similar to our previous report with LPS-induced cells, the supernatants of 70Z/3 cells exposed to DxS contained no detectable immunoglobulin (C. Sidman and C. J. P., in preparation). Second, biochemical analysis of the μ proteins of 70Z/3 cells reveal (1) a cell-surface form, labelled by lactoperoxidase-catalysed iodination, which corresponds in size to membrane μ characteristic of small resting B cells, and (2) biosynthetically labelled intracellular forms which correspond to the smaller precursors of both the secretory and membrane pathways (ref 16, and C. Sidman and C. J. P., in preparation). Analysis using tunicamycin of the non-glycosylated products further revealed a precursor pattern previously described for both membrane and secretory μ^{16} . In this respect 70Z/3 cells are similar to other B cells containing the precursors for both pathways but the final product of only the membrane form¹⁶.

The detection of cIg⁺ sIg⁻ cells which acquire sIg confirms the circumstantial evidence which suggests that this transition normally occurs during B-cell differentiation 7,17,18. Our findings are also consistent with reports that the onset of heavy and light chain synthesis is asynchronous^{12,19}. It is not clear whether the expression of μ chains has a regulatory role in B-cell development before light chain appearance. One report suggests that some pre-B cells may be capable of secreting μ chains¹⁹. Our findings, although different in that 70Z/3 cells do not secrete their μ chains, also suggests the possibility of interaction with the external environment through the variable region of the μ chain. This interaction might occur before synthesis of complete antibody molecules and thus be relevant to theories of clonal abortion, tolerance induction and network formation. Maki et al. have recently shown that whereas μ only fetal liver hybridomas have unrearranged light chain genes, the κ gene of ' μ only' 70Z/3 has already undergone rearrangement¹³. Thus several stages of pre-B cells may exist based on both DNA molecular arrangement and the expression of rearranged gene products.

We do not yet know the incidence of precursors in fetal and adult tissues with properties corresponding to 70Z/3 cells. These cells may represent a transient stage of B-cell maturation which is subject to regulation by factors such as those present in certain serum lots and by mitogens.

We thank Drs M. A. S. Moore and M. Scheid for helpful discussion of these data, and Ms Pamela Kiss and Ms Joanne Albertini for assistance in preparing this manuscript. This work is supported by grants CA-24300, AI-12741 and Research Career and Development Award AI-00265. The Basel Institute for Immunology was founded and is supported by F. Hoffmann-La Roche and Co.

Note added in proof: A human lymphoma has recently been described which also expresses μ chain in the absence of light chains; "A human B-cell lymphoma synthesizing and expressing surface μ chain in the absence of detectable light chain" (Gordon, J., Hamblin, T. J., Smith, J. C., Stevenson, F. K. & Stevenson, G. T. Blood (in the press).)

Table 1 Differential responsiveness of 70Z/3 and 70Z/3.1 to LPS and DxS

	% surface μ^+				
Stimulus	70Z/3	70Z/3-SF	70Z/3.1		
	2	0	0		
LPS(1 μ g ml ⁻¹)	82	0	0		
DxS (50 μg ml ⁻¹)	76	73	76		

Cell cultures were initiated at 2.5×10⁵ ml⁻¹ and exposed to either LPS or DxS for 24 h. Surface μ expression was determined using rhodamine-conjugated [F(ab')2] fragments of goat antibodies. For 70Z/3-SF cells, 70Z/3 cells were grown in serum-free Iscove's modified Dulbecco's medium (Gibco, No. 430-220) supplemented with lecithin/cholesterol, human transferrin (Hoechst) and delipidated bovine serum albumin (Behring, no. TR05) as previously described²⁰. The cells had been growing serum free for 6 weeks at the time of this experiment. For 70Z/3.1 cells, clones of 70Z/3 cells were obtained by initiating growth in RPMI medium (supplemented as described in Fig. 1 legend) containing 0.3% agar (Difco). Approximately 60-75% of the cells formed discrete colonies in these conditions. Clones were picked at day 6, transferred to microwells containing 0.2 ml medium and subsequently maintained in tissue culture flasks.

Hormonal regulation of synthesis of volk proteins and a larval serum protein (LSP2) in *Drosophila*

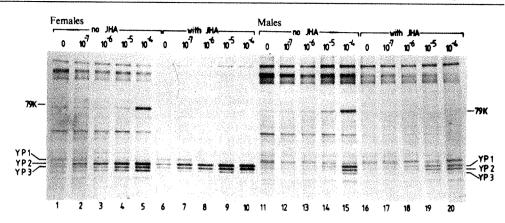

T. Jowett* & J. H. Postlethwait†

Juvenile hormone (JH) and 20-hydroxyecdysone (20-HE) have a wide range of roles in insects. They interact during development to determine the quality of the moult1-4 and both hormones have been implicated in control of yolk protein synthesis and ovarian development. However, their functions vary in different insects⁵⁻⁷. In adult Drosophila, they have specific effects on the haemolymph proteins. Both JH analogue (JHA) and 20-HE stimulate the synthesis and secretion of three yolk polypeptides (YPs) into the haemolymph of females^{8,9}. However, whereas JHA stimulates synthesis of YPs in both the fat body and the ovary, 20-HE stimulates the synthesis only in the fat body 10 the fat body¹⁰, and JH, but not 20-HE, induces YP deposition in oocytes^{9,11,12}. 20-HE, but not JHA, evokes YP synthesis in Drosophila males (which do not normally produce these proteins¹³), and 20-HE treatment of isolated female abdomens stimulates incorporation of ³⁵S-methionine into a protein of molecular weight 79,000 (designated 79K). We have now compared the responses of the YPs and 79K to combinations of JHA and 20-HE given to both male and female Drosophila and show that 79K is a larval serum protein (LSP2) normally secreted by the fat body of third instar larvae. JHA and 20-HE have additive effects on YP synthesis, but JHA antagonizes 20-HE stimulation of LSP2 synthesis. This effect is probably caused by JHA induction of fat body cell death.

In an initial experiment, animals were ligated soon after eclosion, aged for 24 h to allow endogenous levels of hormone to decay and then treated in groups of 16 with increasing amounts of 20-HE in the presence or absence of JHA. After 6 h the haemolymph proteins were labelled by injecting 35S-methionine and finally separated on SDS-polyacrylamide gel electrophoresis (PAGE). This experiment revealed three different effects of the hormone treatments. (1) Incorporation of label into YPs was stimulated additively by 20-HE and JHA in isolated female abdomens (Fig. 1, lanes 1-10, and Fig. 2), confirming earlier reports^{9,10}. (2) Secretion of newly synthesized YPs was also stimulated by 20-HE in isolated male abdomens

Fig. 1 JHA inhibits the 20-HEstimulated label incorporation into 79K but augments that into the YPs. Isolated abdomens were prepared from newly eclosed flies by ligation with nylon thread between the thorax and abdomen, and removal of the head and thorax with scissors. After ageing for 24 h to allow the endogenous hormone evels to decline, abdomens were treated in groups of 16 with different concentrations of 20-HF in 1% ethanol/Ringer's solution. A second set of abdomens was treated with the same concentrations of 20-HE in the presence of a juvenile hormone analogue, ZR-515 (ref. 22) (0.3 µl of an

acetone solution of JHA was added topically to each abdomen giving a final dose of 1.6 ng ZR-515 per abdomen). After a 6-h incubation, the newly synthesized haemolymph proteins were labelled by injecting $1 \mu \text{Ci}^{35}\text{S}$ -methionine per abdomen in *Drosophila* Ringer²³. After a further 2-h incubation, the haemolymph was collected and mixed with sample buffer²⁴. One-quarter of each sample electrophoresed on an SDS-containing 9-15% polyacrylamide gel²⁵; the Coomassie blue-stained gel was dried and autoradiographed. The figure is a photograph of the resulting autoradiograph. Lanes 1-10 and 11-20 are from female and male isolated abdomens respectively. Lanes 1-5 and 11-15 are from abdomens treated with increasing doses of 20-HE alone, while lanes 6-10 and 16-20 are from abdomens treated with increasing doses of 20-HE in the presence of JHA. 20-HE-stimulated label incorporation into YP1, YP2 and YP3 and the 79K polypeptide. Treatment with both hormones together stimulated label incorporation into YPs but not 79K.

(Fig. 1, lanes 11–15), demonstrating that the anterior of the male fly does not mediate the action of 20-HE. JHA alone had no effect in male abdomens (Fig. 1, lanes 11 and 16). Whereas the response to the hormones was approximately additive in females (Fig. 1, lanes 2–5 and 7–10), in males JHA made no consistent alteration to the 20-HE response (Fig. 1, lanes 12–15 and 17–20). (3) 20-HE stimulated synthesis of 79K in both males (Fig. 1, lanes 11–15) and females (Fig. 1, lanes 1–5), but this response was abolished in both sexes by the presence of JHA (Fig. 1, lanes 16–20 and 6–10, and Fig. 2). Thus in young adult haemolymph, the labelling of two simultaneously occurring groups of polypeptides is stimulated by 20-HE, and JHA adds to the 20-HE stimulation for one group of polypeptides but abolishes it for the other.

Because the nature and the site of synthesis of 79K were unknown, experiments were performed to identify the 79K polypeptide. During our work with YPs, we had noted that 79K was always seen in Coomassie blue-stained gels of haemolymph from newly eclosed males and females, but that it gradually disappeared from haemolymph of older animals (see Fig. 1 in ref. 10). This development programme for 79K coincides with that for the larval fat body. About 1,000 larval fat body cells survive metamorphosis but then histolyse in the first few days of adult life under the influence of JH^{14,15}. We thus suspected that 79K might be synthesized and secreted by the larval fat body cells that remain after eclosion. The major proteins synthesized and secreted by the larval fat body are the larval serum proteins (LSPs)¹⁶—LSP1, a hexamer containing combinations of three different polypeptides^{17,18}, and LSP2, a homohexamer¹⁹. As the four constituent polypeptides have estimated molecular weights of 75,000-83,000, it seemed reasonable that 79K seen in adult haemolymph at eclosion was a polypeptide constituent of LSP1 and/or LSP2 which was synthesized and secreted by the surviving larval fat body cells.

To test this hypothesis, ³⁵S-methionine-labelled haemolymph samples from abdomens which had been injected with either Ringer's solution or 20-HE were subjected to immunoelectrophoresis with antisera raised against purified LSP1 and LSP2 and compared with labelled haemolymph from mid-third instar larvae (Fig. 3). Larval haemolymph forms two major precipitin arcs, one corresponding to LSP2 and the other containing the three subunits of LSP1. Immunoelectrophoresis of the adult haemolymph showed that no label was incorporated into LSP1 in isolated abdomens irrespective of treatment with 20-HE. In contrast, LSP2 was heavily labelled in the haemolymph from the 20-HE-treated isolated abdomens and was weakly labelled in haemolymph from control abdomens.

To confirm that the arc formed with anti-LSP2 antisera indeed represented the 79K polypeptide identified by SDS-PAGE, a section of each precipitin arc was cut out of the agar plate and the sample run on SDS-PAGE with some of the original haemolymph samples. The labelled LSP1 precipitin arc from larval haemolymph separated as three distinct polypeptides but each of these was absent from the isolated abdomen haemolymph samples. The LSP2 precipitin arc was labelled in

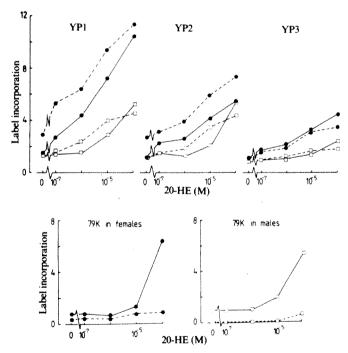

Fig. 2 Quantification of the response to hormone. Autoradiographs of the experiment in Fig. 1 were scanned using a Joyce–Loebl microdensitometer and the label incorporation estimated by measuring the peak areas of the 79K and YP bands. Each point represents the mean of two experimental replicates. Top panel, YPs; bottom panel, 79K. ♠, Female abdomens; □, male abdomens. For both panels a broken line indicates JHA treatment with different concentrations of 20-HE; a solid line indicates 20-HE treatment in the absence of JHA. In females the two hormones stimulated label incorporation into the YPs additively, whereas JHA had no effect on the labelling of YPs in males. In both males and females 20-HE stimulated labelling of the 79K polypeptide but this effect was abolished by simultaneous treatment with JHA.

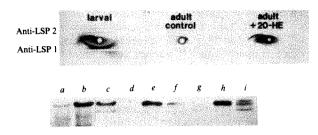

Fig. 3 79K is immunoprecipitated by antisera against LSP2. Labelled larval haemolymph was obtained by injecting mid-third instar larvae with S-methionine dissolved in Ringer and collecting the haemolymph 2 h later. The adult haemolymph was obtained from abdomens which had been ligated at eclosion and allowed to age for 24 h. Controls were injected with Ringer and after 8 h injected with 35S-methionine and haemolymph collected after a further 2 h. The 20-HE-treated abdomens were injected with 10⁻⁴ M 20-HE in 1% ethanol/Ringer 8 h before treatment with label. All haemolymph samples were mixed with unlabelled larval haemolymph, to act as carrier, and immediately subjected to immunoelectrophoresis. They were run in agar on microscope slides with 0.1 M sodium barbitone buffer (pH 8.4) at 80 V for 45 min at 4 °C. After electrophoresis each slot was filled with either anti-LSP1 or anti-LSP2 antisera, raised in rabbits from the purified proteins. After precipitation overnight the white precipitin arcs could be seen, and the agar was washed thoroughly in phosphate-buffered saline and stained with amido-Schwartz, dried and autoradiographed. The resulting autoradiograph is shown in the top panel. Larval haemolymph produced two main precipitin arcs corresponding to each of the LSPs. The adult haemolymph did not show any label incorporation into the LSP1 precipitin arc. A small amount of label was incorporated into the LSP2 arc of the control abdomens while considerably more was found in the haemolymph of those treated with 20-HE. Identical precipitin arcs were cut out of the agar without staining and mixed with SDS buffer before running on an SDS-containing 9% polyacrylamide gel. The gel was dried and autoradiographed. The 79K region of the resulting autoradiograph is shown in the lower panel: a, haemolymph from the control abdomens; b, haemolymph from abdomens treated with 20-HE; c, labelled mid-third instar larval haemolymph; d, LSP1 precipitin arc from 20-HE-treated abdomens; e, LSP2 precipitin arc from 20-HEtreated abdomens; f, LSP2 precipitin arc from control abdomens; g, LSP1 precipitin arc from control abdomens; h, LSP2 precipitin arc from larval haemolymph; and i, LSP1 precipitin arc from larval haemolymph. The LSP1 precipitin arc from larval haemolymph separates into the three LSP1 subunits but label is absent from this protein in the adult abdomens. The LSP2 precipitin arc is present in the haemolymph from the abdomens and label incorporation is stimulated by the treatment with 20-HE.

both adult haemolymph samples and co-migrated with LSP2 from larval haemolymph. In addition, the LSP2 from 20-HEtreated abdomens contained considerably more label than that from abdomens injected with Ringer alone.

These experiments have shown that both JHA and 20-HE act additively on YP synthesis. They also provide the first evidence that the appearance of LSP2 is also hormonally regulated, and that, in contrast with the YPs, its synthesis is stimulated by 20-HE only and abolished by JHA.

It follows from our observations that the larval fat body persisting in the newly eclosed adult is still capable of synthesizing LSP2. It also seems that the absence of LSP2 synthesis in the intact early adult is primarily because of the endogenous secretion of JH since merely ligating the abdomen causes a partial stimulation in synthesis of LSP2 and addition of JHA abolishes both this and the response to 20-HE. Once the source of JH has been removed by isolation of the abdomen, the larval fat body is able to synthesize LSP2 in response to 20-HE. Thus, although the effect has only been demonstrated at a developmental stage when the LSP2 gene is no longer active because of the presence of JH, it nevertheless suggests that the initial appearance of LSP2 may also be ecdysone induced. This is consistent with the observed ecdysone pulse at the second larval moult shortly before the appearance of LSP2 at the beginning of the third instar²⁰

If 20-HE is indeed the hormonal trigger for LSP2 synthesis at the onset of the third larval instar, then either the titres of JH must be low or the larval fat body at that stage refractory to any naturally occurring JH. The latter is quite likely as larval fat body transplanted from third instar larvae into adults in contrast to larval fat body which has been through metamorphosis 15,21 not susceptible to JH-induced histolysis. As the susceptibility of the larval fat body to JH changes during pupation, the inhibition of the response to 20-HE could provide a means of monitoring the transition. The simplest explanation for the inhibitory action of JHA on the stimulation of LSP2 by 20-HE is that JH triggers cellular responses that lead to death of the remaining larval fat body15. However, this action of JH at the molecular level may be complex because the JH-induced death of the larval fat body is blocked by inhibitors of protein synthesis15

Study of the appearance of LSP2 associated with the changes in the susceptibility of the larval fat body to these two major hormones should elucidate their actions on specific gene expression during development.

We particularly thank D. Sears and K. Bekkedahl for technical assistance, and Dr Paul Shirk for comments during the work. We also thank Dr David Roberts for invaluable suggestions and for supplying the anti-LSP antibodies. The work was supported by NIH grant GM 21548 to J.H.P.

A homoeotic mutation transforming leg to antenna in Drosophila

Gary Struhl

MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

Insects are thought to have evolved from millipede-like ancestors composed largely of a series of identical, leg-bearing segments. This view of insect evolution is supported by the existence of homoeotic mutations which transform particular abdominal and head segments into thoracic segments 1-3. Such transformations are described as atavistic3, because they return specialized segments to a more primitive condition. In Drosophila, several dominant mutations of the homoeotic locus Antennapedia (Antp) lead to a transformation of the antenna to the second leg⁴⁻⁸. Here, I describe the isolation and characterization of apparent null alleles of the Antp locus. These mutations lead to a homoeotic phenotype which is the reverse of the dominant Antennapedia phenotype, namely, they result in the transformation of the second leg into an antenna but do not alter the development of the normal antenna itself. This result indicates that (1) the product of the wild-type Antp gene is normally active in the mesothorax where it promotes a mesothoracic pathway of development instead of an antennal pathway, (2) the Antp⁺ gene product is normally absent or inactive in the antenna, and (3) dominant mutations of the locus result in the inappropriate activity of the wild-type gene product in the antenna, and hence in the transformation of antenna to leg. Thus, unlike most other homoeotic gene products, the product of the Antp+ gene seems to promote, not to repress or modify, an atavistic condition.

Table 1 Homozygous Antp^{Ns+RC3} clones in the eye-antenna and mesothorax

Compartment	No. of blastoderm clones*	No. of first instar clones*	Phenotype†
Eye-antenna $(A + P)$	18	43	Normal
Leg 2 (A)	16(24)	18(24)	Antennal
Leg 2 (P)	14(15)	8(8)	Antennal
Notum + wing (A)	1(2)	9(16)	Abnormal

Marked clones of cells lacking the Antennapedia $^+$ gene were obtained as follows. Embryos or larvae of the genotype $Ant^{Ns+RC3}\,e^{11}/Ki\,Sb^{63b}$ $M(3)w^{124}$ were irradiated at appropriate times after egg laying $(3\pm$ 0.7 = blastoderm stage; 24-48 h = first instar) (see Fig. 1 for description of mutations). All the mutations are located on the right arm of the third chromosome; because Ki is positioned closest to the centromere, mitotic recombinations which occur between Ki and the centromere can give rise to homozygous Ki^+ cells which must also be homozygous for $Antp^{Ns+RC3}$, Sb^+ , e^{11} and $M(3)w^+$. 2,128 flies were screened following irradiation with 500 rad at the blastoderm stage, and 959 flies were screened following irradiation with 1,000 rad during the first larval instar. Clones lacking the Antp+ gene were identified under the dissecting microscope by the appearance of marked bristles and because they frequently disrupted the normal morphology. (Clones which mark, but do not transform, the distal portions of leg are difficult to identify under the dissecting microscope, and hence may have been missed.) All clones were mounted and inspected under the compound microscope. A comparable analysis of first instar clones of a second revertant allele, , gave similar results.

*Number of clones in which some of the cells showed the normal, antennal or abnormal phenotype indicated in the last column (in those compartments in which some, but not all, of the clones were normal, the total number of clones is indicated in parentheses).

†Clones in the anterior compartment of the second leg were classified as antennal only when they formed antennal tissue. Clones in the posterior compartment of the second leg were classified as showing the antennal phenotype if they removed portions of the compartment—even when antennal tissue was not found (see text). The abnormal phenotype observed in notum clones is described in the text.

Mutations which eliminate most, or all, of the activity of the Antp⁺ gene were obtained using the general procedure of selecting phenotypic reversions of a dominant mutation9. This approach has been used by others 10,11 to isolate apparent null alleles of the Antp locus. Homozygous Antp No males were treated with the mutagen ethyl methane sulphonate (EMS)12 and outcrossed to appropriately marked females. From among ~10,000 F₁ progeny, 35 phenotypic revertants were found; 12 of these progeny were found to carry 'revertant' alleles of the $Antp^{Ns}$ mutation (designated $Antp^{Ns+RC1, 2, 3, \dots, 12}$). Three lines of evidence suggest that these revertant alleles eliminate most, or all, of the wild-type activity of the Antp locus. First, they arose with the expected frequency of null mutations in a single gene following a standard EMS mutagenesis¹³. Second, all these mutations are lethal over a deficiency of the Antp locus (Df(3R)4Scb; G. Jürgens, personal communication), as well as over other recessive lethal mutations of the locus (for example, Antp^B, Antp^{73b}, Antp^{Scx}). Third, animals which are homozygous or hemizygous for any of these reversions die as first instar larvae and show the characteristic terminal phenotype caused by loss of the wild-type Antp gene¹⁴ (but not those phenotypes associated with the loss of neighbouring genes, such as Scr, R14)¹⁴. It is possible that reversions of the $Antp^{Ns}$ mutation may eliminate more than one genetic function; however, in the absence of substantiative evidence that the Antp gene is itself complex, it is simplest to treat these reversions as mutations in a single gene.

The consequences of removing the wild-type Antp gene from particular cells during development have been studied by generating clones of cells homozygous for $Antp^{Ns+RC}$ mutations in animals otherwise heterozygous for the mutation (see Fig. 1, Table 1). Cells belonging to these clones were independently marked using the bristle mutations Kinked, Stubble, $Minute(3)w^{124}$ and ebony (Fig. 1, Table 1; see refs 15 and 16 for descriptions of mutations). In addition, the Minute technique of

clonal analysis¹⁷ was used, so that clones of homozygous, $Antp^{Ns+RC}$ $M(3)w^+$ cells grew faster than surrounding, $Antp^{Ns+RC}/M(3)w^{124}$ cells, and hence formed large portions of the adult compartments^{18,19}. Clones were induced at the blastoderm stage as well as at later times during larval development. The results are shown in Fig. 1 and Table 1 and are described below.

First, clones in the eye-antennal segment were normal even when they were large enough to form most of the antenna, head capsule and maxillary palp (Fig. 1b, c). Similarly, clones in the proboscis, as well as at least the first six abdominal segments, were normal.

Second, clones in the anterior compartment of the second leg frequently transformed some parts of the leg into corresponding antennal structures (for example, distal portions of the leg, such as the tarsus, were transformed into tissue characteristic of the distal antenna, such as the third antennal segment (Fig. 1d-f)). However, only some of the marked cells showed the homoeotic phenotype while the remaining marked cells formed normal second leg structures (Fig. 1d, e).

Third, clones in the posterior compartment of the second leg were generally associated with the absence of parts of the posterior compartment; in a few cases, vesicles of antennal tissue were also found associated with the clone (Fig. 1g). Note that the posterior compartment of the antenna is relatively small (Fig. 1c)²⁰. Consequently, a transformation of the posterior leg compartment into the posterior antenna compartment is expected to replace the leg compartment with only a small amount of antennal tissue.

Fourth, following irradiation at the blastoderm stage, the number of clones obtained in the anterior wing and notum (the dorsal derivatives of the mesothorax) were disproportionally small compared with the number of clones obtained in other appendages (Table 1). This result suggests that most blastoderm clones induced in the wing and notum primordium were lost during development or prevented the emergence of the flies bearing them. Wing and notum clones induced during the first larval instar and later, were found with similar frequencies to clones induced at the same time in other appendages. However, most of these clones showed abnormal patterns of notum bristles and in a few cases, atypical bristles were also observed.

Finally, clones induced during the blastoderm stage in the first and third legs were abnormal in about half the cases. Generally, such abnormal clones were associated with the absence of portions of the leg and with atypical cuticular patterns which could not be identified.

The principal result is that the phenotype of apparent null mutations of the *Antennapedia* locus (second leg transformed into antenna) is the reverse of that of dominant mutations of the

Table 2 Control of antennal versus second leg development by the $Antp^+$ gene product

The state of the s	Ante	nna	Second leg		
Genotype	Antp ⁺ gene product	Structure formed	Antp ⁺ gene product	Structure formed	
Wild type $Antp^{Ns}/+Antp^{-}/Antp^{-}$	Absent (Present) Absent	Antenna (Leg 2) Antenna	Present Present Absent	Leg 2 Leg 2 Antenna	

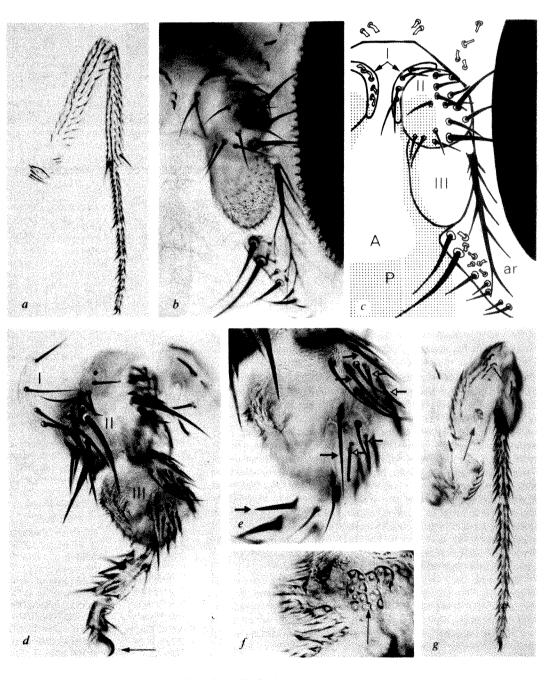

Model for the control of antennal versus second leg development by the $Antp^+$ gene product. In both the antennal and second leg, presence (and activity) of the $Antp^+$ gene product leads to leg development whereas absence of the active gene product leads to antennal development. Normally, the $Antp^+$ gene product is absent (or inactive) in the antennal primordium, but present (and active) in the leg primordium. Mutations conferring the dominant Antennapedia phenotype result in the presence of active gene product in the antenna leading to an antennal to leg transformation (because this transformation is variable and incomplete it is likely that the gene product is only partially expressed or partially active in the antenna). Apparent null alleles of the $Antp^+$ gene result in the absence of active $Antp^+$ gene product in both the antenna and second leg, leading to a transformation of the leg into antenna.

locus (antenna transformed into second leg). This situation parallels that of dominant and recessive mutations of several of the genes of the bithorax complex1, and leads to the following conclusions: (1) in wild-type flies, the Antp+ gene product is normally active in the mesothorax where it promotes mesothoracic as opposed to antennal development, but absent or inactive in the eye-antennal segment, and (2) mutations of the locus which confer a dominant Antennapedia phenotype result in inappropriate activity of the Antp⁺ gene product in the antenna, thereby transforming the antenna into a second leg (Table 2). These conclusions must be considered in the light of the homoeotic phenotypes of embryos lacking the Antp⁺ gene. Wakimoto and Kaufman¹⁴ have described this phenotype as a partial transformation of the meta- and mesothorax into prothoracic segments, and concluded that the Antp+ gene is normally required in the meso- and metathorax for promoting a normal as opposed to a prothoracic pathway of development. If their interpretation of the embryonic phenotype is correct, the results presented here would indicate that the $Antp^+$ gene product controls one developmental alternative (mesothorax instead of prothorax) in embryonic cells giving rise to the larval cuticle, and another developmental alternative (mesothorax instead of eye-antenna) in imaginal cells giving rise to the adult cuticle.

A second result of interest is that the leg-to-antenna transformation observed in clones lacking the $Antp^+$ gene is shown by some, but not all, of the cells belonging to the clone, the remaining cells forming normal second leg structures. Although there are many possible explanations for this apparent non-autonomy, the simplest is that the wild-type Antp gene product can pass between cells, thereby allowing heterozygous cells to rescue neighbouring mutant cells. This interpretation is supported by the observations that large clones generally formed antennal structures whereas small clones did not (data not

Fig. 1 Phenotype of somatic clones lacking the Antennapedia+ gene in the antenna and second leg. a, Wild type, second leg $\times 56$, b, c, Fly's head bearing a marked clone induced at the blastoderm stage which forms a normal antenna and part of the head capsule. Cells of the clone are marked by the recessive mutation $ebony^{11} (e^{11})$ which darkens the normal colour of cuticular structures, particularly bristles; cells outside the clone are marked by the dominant mutations Kinked (Ki), Stubble 63b (Sb 63b) and Minute (3) w^{124} (M(3) w^{124}) which together result in short, stunted bristles (see refs 15, 16 for descriptions of mutations). In c, bristles belonging to the clone are blacked in. whereas bristles outside the clone are drawn in outline. The three antennal segments (I, II and III), the arista (ar) and the anterior unshaded) and posterior (P; shaded) compartments of the eye-antenna are indicated inc. ×186. d. shown), and that mutant cells which were untransformed were generally positioned at the periphery of mutant clones, next to heterozygous cells (for example, Fig. 1e). In this context, it is interesting that regions of the leg such as the distal tarsus and claw which were never transformed (Fig. 1d) are situated next to the anteroposterior compartment boundary21, and hence, are always adjacent to heterozygous cells which may rescue the mutant phenotype. The possibility that the wild-type Antp gene product can pass between cells also provides a plausible explanation for the results of Kauffman and Ling²², who found that wild-type (+/+) clones in the antennae of $Antp^{Ns}/+$ flies often formed leg tissue.

Studies of genes of the bithorax complex have provided support for the supposition that a series of thoracic-like segments was progressively modified during evolution to form the sequence of specialized segments of the insect abdomen and thorax1. If a similar process modified more anterior, thoracic-

like segments into the specialized segments of the head, it is possible that a small number of control genes may be responsible for specifying the development of the head segments. Clearly, the products of such head promoting genes should not function in the thoracic segments, otherwise they also would develop into head segments. It is possible, therefore, that the product of the Antp⁺ gene normally acts in the thorax to repress the function of head promoting genes, but is absent (or inactive) in the head segments where the functions of these genes are required for normal development.

Intervening sequences in ribosomal RNA genes and bobbed phenotype in Drosophila hydei

Gerald Franz & Werner Kunz

Institut für Genetik, Universität Düsseldorf, Universitätsstrasse 1, D-4000 Düsseldorf, FRG

The 'bobbed' (bb) mutation in Drosophila is represented phenotypically by shortened and abnormally thin scutellar bristles and by delayed development. There is a direct correlation between bristle size and ribosomal RNA (rRNA) synthesis1, and the bb mutation was at first explained as a deficiency of rRNA genes (rDNA)2. However, the bb phenotype can occur in Drosophila melanogaster and Drosophila hydei³ with high rDNA content, while phenotypically wild-type flies are known with few rRNA genes, suggesting that what matters is not the number of rRNA genes but their transcriptional activity. In D. melanogaster, it has recently emerged that rRNA genes interrupted by an intervening sequence are not transcribed4. We now report that in D. hydei, the length of the scutellar bristle is directly proportional to the number of rRNA genes without this intervening sequence.

D. hydei has three clusters of rRNA genes (nucleolar organizers, NOs), one on the X and two on the Y chromosome^{5,6}. We have previously described flies containing only Y-chromosomal NOs which were not bobbed in spite of a low rDNA content. In contrast, flies with only X-chromosomal NOs, containing significantly more rDNA, were bobbed3. Clearly in D. hydei, the NOs on the Y and X chromosomes do not have a comparable influence on the bobbed phenotype.

Many X-chromosomal rRNA genes in D. hydei contain an intervening sequence 6 kilobases (kb) long (ivs + genes)7, but in several genotypes with only Y-chromosomal NOs, no ivs+ rRNA genes have been detected. As in D. melanogaster, ivs+

genes in D. hydei do not seem to be significantly transcribed8. Consequently, the X-chromosomal NO, in contrast with the Y-NO, does not seem to be completely functional with respect to rRNA transcription.

Total rRNA gene numbers were determined by filter saturation hybridization experiments between ¹⁴C-DNA from whole adult flies and 28S ³H-rRNA. To eliminate variation of bb expression within each of our laboratory strains, each investigated strain was newly started from a single pair mating, and flies from the F₂ or F₃ generation used. Among 20 genotypes investigated, 11 had either the wild-type scutellar bristle length of 0.57 mm or very close to it, in spite of the fact that their rDNA content varied from 210 to 1,113 genes per two chromosome sets (Fig. 1, Table 1). Two genotypes showed slightly reduced bristle lengths (0.50 and 0.52 mm), although their rRNA gene number was very high (780 and 1,067). Flies from seven other genotypes were phenotypically clearly bobbed, with bristle sizes

n, Number of flies of which the two posterior scutellar bristles have been measured. F, number of filters which have been measured per genotype to determine the rDNA percentage. G, number of gels used for Southern transfer, hybridization and determination of the ivs "/ivs rRNA gene relationship.

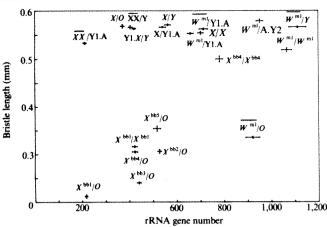

Fig. 1 Plot of rRNA gene numbers per two chromosome sets of different genotypes of D. hydei relative to the length of the two posterior scutellar bristles. The bristle length of 10-100 individuals of each genotype was measured under a dissecting microscope. DNA from several hundred flies of each genotype was extracted, nick-translated with deoxy-14C-ATP, and 2-µg samples were loaded on to nitrocellulose filters, essentially following the methods described previously 13. To determine the per cent rDNA in the different genotypes, the DNA was hybridized to 28S 3HrRNA from cultured cells of D. melanogaster. Hybridization was in the saturation range at Rot values between 0.4 and 0.5 mol RNA s I⁻¹. The measured d.p.m. values have been corrected for non-specific background binding and for DNA loss during the hybridization procedure. The gene numbers have been calculated on the basis of a diploid genome size of 0.5 pg DNA and on the estimation that the X chromosome includes 17% and the Y chromosome 9% of the DNA of a diploid D. hydei genome²⁰ Chromosome symbols: \overline{XX} , attached \overline{X} , a chromosome without rDNA; w^{m1} , \overline{X} chromosome with two NOs²¹; w^{m1} , attached w^{m1} chromosome, carrying two NOs; Y1·X, Y1·A and A·Y2, Y-X and Y-autosome translocation chromosomes, each with only one Y-chromosomal NO.

between 0.21 and 0.35 mm. However, their rRNA gene number was of the same order of magnitude as that of wild-type flies: between 217 and 921. Nine genotypes of phenotypically wild-type flies had either the complete Y chromosome with two NOs or a Y-chromosomal fragment with one NO; two genotypes with wild-type bristles had only X-chromosomal NOs. The seven genotypes whose flies were distinctly bobbed all contained only X-chromosomal NOs. The fact that six of them had more rDNA than the wild-type X/O male demonstrates that not only Y-chromosomal but also X-chromosomal rRNA gene number is not directly correlated with the bobbed phenotype.

To determine the relative amounts of ivs+ and ivs genes, the DNA from bobbed flies and from X/O or X/X wild-type flies was double-digested with EcoRI and PstI. The fragments were separated on 1% agarose gels, transferred to nitrocellulose filters according to Southern⁹ and hybridized with a ³²P-rDNA fragment (pDh2-A4) cloned from D. hydei 10 (Fig. 2). This fragment, which consists mainly of the 28S coding region, hybridizes to an EcoRI-PstI fragment of 5.4 kb with ivs genes. With ivs + genes it hybridizes to a slightly smaller 4.8-kb band (Figs 2 and 3). The use of such similar-sized fragments for quantification of DNA after Southern transfer reduces the danger of an unequal transfer to nitrocellulose of DNA molecules with widely differing molecular weights. The two bands were quantified by scanning the autoradiograms on a Joyce-Loebl Chromoscan 200. The absolute ivs and ivs gene numbers were calculated using the values from Fig. 1, giving the results shown in Table 1. All bobbed genotypes possess few ivs genes compared with the wild type.

When only the *ivs* gene number of each genotype is plotted relative to the bristle length, a direct proportionality between the gene number and phenotypic *bobbed* expression is evident in the range between 30 and $\sim 150~ivs$ genes (Fig. 4). The correlation coefficient in this range is 0.95. The *bobbed* phenotype is

Table 2 ivs rRNA gene number per two chromosome sets in salivary gland DNA

	ivs rRNA gene	
Genotype	number \pm s.e.m.	F; G
X/X	$149 \pm 8 (13)$	21; 3
X/O	143 ± 5	5; 2
X^{bb4}/X^{bb4}	104 ± 7	9; 3
X^{bb} $^4/O$	48 ± 5	10; 3

X/O and X/X constitutions are compared in the wild-type and the bb4 stock. The total rDNA percentage was measured in DNA from hand-dissected salivary glands from third instar larvae by filter saturation hybridization (for methods, see ref. 13). The ivs rRNA gene content was determined photometrically after EcoRI-PstI digestion, gel electrophoresis, Southern transfer, hybridization and autoradiography as described for DNA from whole flies. The values have been corrected for non-specific background binding, for DNA loss during the hybridization procedure and for differences in genome size. As only the euchromatic portion of the genome is involved in polytenization to chromosome sets in a polyploid nucleus are 0.37 pg DNA in an X/X genotype of D. hydei and 0.33 pg DNA in an X/O genotype (values calculated from the data of Mulder et al. 20). F; G, for explanation, see Table 1 legend.

no longer expressed when $\sim 200 \, ivs^-$ genes are reached. A further increase in gene number $(X/O:220, X/X:428 \, ivs^-$ genes) does not result in larger scutellar bristles (Table 1).

Gene numbers have been measured on DNA extracted from whole flies, which contain both diploid and polyploid tissue. However, rDNA percentages measured in the DNA from whole flies differ from those in polyploid tissue as during polytenization¹¹ and polyploidization¹² in D. hydei, the rDNA is under-replicated. Furthermore, in particular genotypes the rDNA undergoes disproportionate replication: 'gene compensation' increases the rDNA content in some diploid organs relative to polyploid organs¹³ and 'independent rDNA polyploidization' raises the rDNA percentage in polyploid cells relative to diploid cells^{13,14}. As the bristle-forming cells in Drosophila are polyploid¹⁵, the rRNA gene number in polyploid tissue rather than the average number in whole flies should directly influence the bristle length. However, in genotypes without gene compensation or independent polyploidization, the amount of rDNA in whole flies is proportional to that in polyploid tissue. Thus, in such genotypes measurements on whole flies are sufficient.

Because gene compensation in D. hydei has hitherto been only observed with Y-chromosomal $NOs^{13,16}$, we selected genotypes with only X-NOs for our investigations. It is less easy to exclude independent rDNA polyploidization, because this process occurs with both Y- and X-chromosomal NOs^{13} . For example, the ivs^- rDNA percentage in whole X/O males is almost exactly half that in X/X females (Table 1), but in salivary glands the ivs^- rRNA gene numbers of both genotypes were the

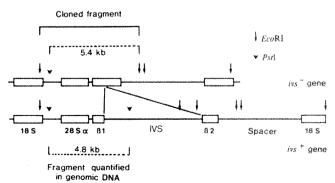

Fig. 2 Schematic diagram showing the two types of rRNA gene with their *EcoRI* and *PstI* restriction sites¹⁰. The indicated cloned fragment (pDh2-A4) was used for hybridization (see Fig. 3). For quantification of the two fragments in genomic DNA, it was taken into consideration that the 4.8-kb fragment hybridizes only partially to the cloned fragment. IVS, intervening sequence.

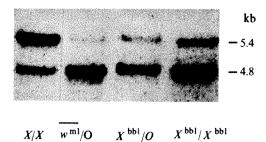

Fig. 3 Autoradiogram of EcoRI-Pst I-digested DNA hybridized with the cloned fragment pDh2-A4 (ref. 10) (see Fig. 2), demonstrating different ivs //ivs f gene relationships in four genotypes. In this experiment, 1 µg of nuclear DNA from whole adult flies of each genotype was loaded on 1% agarose gels, transferred to a filter and hybridized. The hybridization conditions used were: (1 μ g cloned DNA in 10 ml 2×SSC (1×SSC=0.15 M NaCl, 0.015 M Na citrate, pH 7.0), 0.2% SDS, 1× Denhardt's solution; 40 h. The measured relationship of the two fragments within the genotype was independent of the amount of input DNA. For tracing on the Joyce-Loebl Chromoscan, autoradiograms were used only where the film density was linear with increasing exposure time.

same (Table 2). If such independent rDNA polyploidization also occurs in genotypes with bobbed X chromosomes, the difference in bristle length between X/O and X/X constitutions measured in bobbed-1 and bobbed-4 stocks (Fig. 4) is difficult to understand.

As it is very difficult to determine gene numbers directly on bristle-forming cells, we used a representative polyploid tissue, salivary glands, to determine the ivs rRNA gene numbers in our bobbed-4 stock. We found that X^{bb4}/X^{bb4} females have twice as many ivs rRNA genes per chromosome set as X^{bb4}/O males (Table 2). Thus the bobbed-4 X chromosome differs from the wild-type X chromosome by being replicated proportionally during polyploidization with respect to its ivs rRNA genes. The bobbed chromosomes in the other stocks probably behave similarly, so that bobbed flies with low ivs rRNA gene numbers also have low numbers in their polyploid tissue.

Note that none of our investigated genotypes has a low number of both types of rRNA gene (Table 1). Genotypes with low ivs gene numbers have relatively high percentages of ivs genes (81-92%), whereas the wild type has only 40% ivs genes. It is possible that the two types of rRNA gene change their degree of multiplicity in a dependent manner; distinct loss in ivs genes (resulting in the bobbed phenotype) seems to be accompanied by an expansion of ivs + genes. Further experiments are being done to investigate this possible correlation in stocks where spontaneous bobbed mutations occur. Such a correlation would explain the observation¹⁷ that the bobbed mutation in D. hydei is almost exclusively associated with the

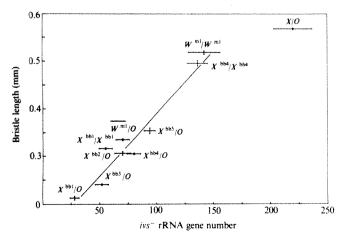

Fig. 4 Direct correlation between ivs rRNA gene number per two chromosome sets and the length of the two posterior scutellar bristles of the same genotypes as in Table 1.

X-chromosomal NO. Only two bobbed mutants of the Y chromosome have hitherto been recorded18. In contrast, in D. melanogaster bobbed Y chromosomes are frequent². In this species, ivs+ genes also occur in the Y-chromosomal NO, whereas in all genotypes hitherto investigated in D. hydei, the Y-NOs seem to be completely free of ivs + rRNA genes.

Multiple copies of iso-insertion sequences of IS1 in Shigella dysenteriae chromosome

Hisako Ohtsubo, Kate Nyman, Włodzimierz Doroszkiewicz & Eiichi Ohtsubo

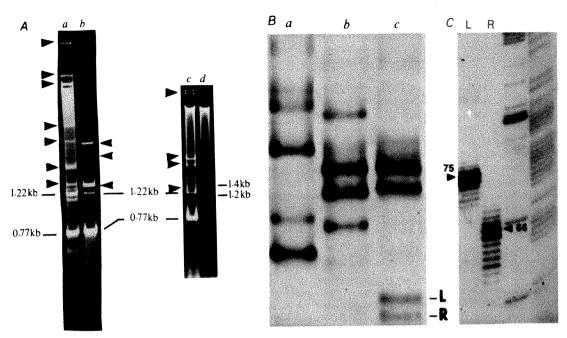

Department of Microbiology, School of Medicine, State University of New York at Stony Brook, Stony Brook, New York 11794, USA

The insertion sequence, IS1, which is 768 base pairs(bp) long1, is the smallest active translocatable DNA element in bacteria (for review see ref. 2), and appears as a repeated DNA sequence in some Enterobacteriaceae species³. In particular, most Shigella species contain more than 40 copies of a sequence that hybridizes to $IS1^3$. Here, we report the isolation of various repeated sequences from the Shigella dysenteriae chromosome and the DNA sequence analysis of the class, which is abut 770 bp long. The results demonstrate that there are two major types of sequence in this class; one is identical to IS1 except for 10-bp substitutions and is present in about 50 copies in the chromosome; the second sequence, 766 bp long, is repeated more than 150 times and has ~55% homology to IS1 on the nucleotide sequence level. Because of this high degree of homology, we call these 'iso-insertion sequences' of IS1. Further examination of the nucleotide sequence reveals common coding frames between these sequences, suggesting the existence of two genes that are required for multiplication of these sequences.

Examination of Sh. dysenteriae DNA by electron microscopy after denaturation and renaturation revealed many singlestranded loop structures with duplex stems, indicative of the presence of inverted repeat sequences4. Of the 70 duplex stems examined, 44 formed a distinguishable peak at 0.77 ± 0.06 kilobases (kb) in the histogram of length versus number of molecules. This size category of inverted repeat sequence comprised 3.94% of the total DNA strands measured. Assuming that the Sh. dysenteriae chromosome is the same size as that of Escherichia coli, namely 2.5×10^9 molecular weight (M_r) or 4×10^6 kb (ref. 5), the estimated number of copies of these inverted repeat sequences is ~200 per chromosome.

We then used an S₁ nuclease digestion technique to purify the inverted repeat sequences on the chromosomes (see Fig. 1 legend). Figure 1A shows the repeated sequences purified from

Fig. 1 A, 1.4% agarose gels, showing bands of duplex DNA isolated from Sh. sonnei (a), Sh. dysenteriae (h. c) and F. coli K-12 (W3110) (d) chromosomes. The duplex DNAs were prepared as follows. The chromosomal DNA first isolated by the method described by Saito and Miura⁶, dissolved in 10 ml of TE buffer containing 0.01 M Tris (pH 7.2) and 0.001 M EDTA, titrated to pH 12.3 with 2 M NaOH at room temperature further incubated for 15 min: The solution was then neutralized with 2 M HCl to pH 7.0. The Na+ concentration in the DNA solution was adjusted to 0.3 M with 3 M NaCl and the solution incubated at 65 °C for 1 min for renaturation of inverted DNA sequences on the DNA strands. The singlestranded DNA in the solution was digested at 37°C for 1 h with 50 U per μg DNA of S. nuclease in a

buffer containing 40 mM sodium acetate (pH 4.6) and 4.5 mM ZnCl₂. After extraction of the solution with phenol saturated with TE buffer, the DNA was precipitated with ethanol and then suspended in 1 ml of TE buffer. 7 ml of 0.12 M sodium-potassium phosphate buffer (Na-P buffer, pH 6.8) containing 2 ml of hydroxyapatite (HAP) suspension (Bio-Rad) was added to the DNA solution and incubated at 65 °C for 30 min. The solution was occasionally stirred with a glass rod to enhance the efficiency of adsorbing double-stranded DNA. The HAP-DNA complex was precipitated by centrifugation and resuspended in the Na-P buffer and the adsorption step above was repeated three times. Double-stranded DNA was then eluted from the HAP in 5 ml of 0.4 M Na-P buffer (pH 6.8) by incubation at 65 °C for 30 min. The elution step was repeated and a total of 10 ml of eluate saved. The solution was concentrated to 2 ml in dialysis tubing which was embedded in polyethylene glycol powder (Carbowax 6000, Bio-Rad), followed by dialysis against TE buffer. After precipitation of the DNA with ethanol, the DNA was resuspended in 200 µl of TE buffer. 10 µl of the solution was used for gel electrophoresis. The above procedure also extracts the plasmid duplex DNAs, present in the bacterial cells. The bands corresponding to plasmid DNA linear, open and closed circular configurations are shown by solid triangles. B, autoradiograms of 6% polyacrylamide gels showing 5'-3'P-labelled fragments of purified inverted repeat DNA sequences of the Sh. dysenteriae chromosome which were cleaved with HaeII (a), HpaII (b) and AluI (c), respectively. C, autoradiograms of 10% polyacrylamide-7 M urea gel containing the two small 5'-3'P-labelled AluI fragments, R and L, which were denatured with alkali and heated at 95 °C after elution of DNA bands shown in Bc. The ladders of bands (differing by one nucleotide in size) suggest that the 5' ends of these fragments are actually heterogeneous. (Ladders seen in two other lanes on the right are size markers that were obtained

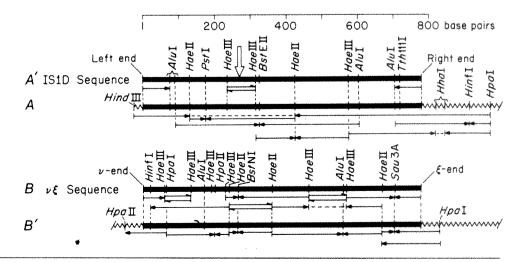

Sh. dysenteriae, Shigella sonnei and E. coli K-12 chromosomal DNA after gel electrophoresis. It is clear that all produce a number of gel bands similar in size to known insertion sequences such as IS1, IS2 and IS3. Note, however, that Sh. dysenteriae (also Sh. sonnei) produces an extremely dense band of DNA about 770 bp long.

We purified the 770-bp sequences of the Sh. dysenteriae chromosome, labelled the 5' ends of the DNA with ³²P and cleaved with various restriction endonucleases. As shown in Fig. 1B, electrophoresis and autoradiography showed two pairs of bands, suggesting that DNA from the 770-bp region is composed of two major sequences that yield different cleavage patterns for the enzymes used. Ethidium bromide staining of these digests revealed two major groups of gel bands with

different intensities (data not shown). The fragments from each group had a sum molecular length of about 770 bp. The ratio of the two components was estimated as 1:3 from the autoradiogram.

Restriction mapping revealed only a single difference between the minor 770-bp sequence and the IS1 sequenced by H.O. and E.O.¹. A HaeIII site absent in the minor fragment (we named this IS1D) was present in IS1 (ref. 1) (we now call this IS1R) (see Fig. 2A). However, the map of the major 770-bp component (which we call $\nu\xi$ in order to assign an orientation to this sequence) was completely different (see Fig. 2B). The same results were obtained using restriction fragments of the Sh. dysenteriae chromosomal DNA which had been cloned into the plasmid pBR322 (see Fig. 2).

Fig. 2 A and A' show cleavage maps of IS1D purified by S nuclease and of IS1D present in a HindIII fragment cloned into pBR322, respectively. In A', the Sh. dysenteriae unique sequence is shown by sawtooth lines. Note that HaeIII site at the position indicated by a vertical open arrow is present in IS1R but is absent in IS 1D. B and B' show cleavage maps of the $\nu\xi$ sequence purified by S_1 nuclease and of that isolated as a BamHI fragment cloned into pBR322, respectively. In B' the sawtooth lines represent the unique sequence of the Sh. dysenteriae The chromosome. numerous horizontal arrows indicate the strategy used for determining the nucleotide sequence of IS1D and vE.

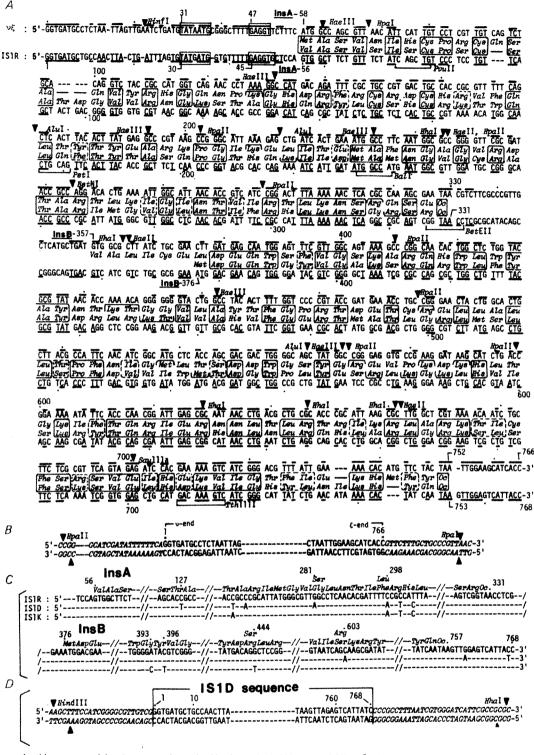

Fig. 3 A, the entire nucleotide sequence of the $\nu\xi$ sequence determined by the method of Maxam and Gilbert?. The sentence is aligned with the nucleotide sequence of ISIR, which has previously been determined, to indicate the sequence homology between them (see lines on the common nucleotides between them). The two sequences encode two common frames, insA and insB, coding for hypothetical amino acid sequences as shown. Homologous amino acids are boxed. B, a part of $\nu\xi$ and unique chromosomal sequence (italic letters) in the fragment cloned into pBR322. C, critical parts of the ISIR sequences together with the amino acid sequences of InsA and InsB. Nucleotide sequences of ISID and ISIR differ from ISIR as shown. Some base substitutions cause amino acid changes as indicated. D, a part of the ISID sequence as well as a unique chromosomal sequence (italic letters) of the Sh. dysenteriae chromosome which has been cloned into pBR322.

Different regions of the $\nu\xi$ sequence were labelled with ^{32}P and used as probes to identify $\nu\xi$ in the chromosomes of various Shigella species and the E. coli K-12 strain, JE5519, using the Southern blotting and hybridization techniques that we have previously used³. The $\nu\xi$ probes hybridized with many EcoRI restriction fragments of Sh. dysenteriae DNA, but the pattern of these fragments was completely different from that previously seen when an IS1R probe was used. Also, the $\nu\xi$ probe hybridized with only one EcoRI restriction fragment from Shigella flexneri and Shigella boydii and none from Sh. sonnei or JE5519

(data not shown), although several restriction fragments of these four species hybridized to IS1 R^3 . These results suggest that $\nu\xi$ does not cross-hybridize with sequences which hybridize to IS1 probes.

We next used the Maxam and Gilbert method⁷ to determine the entire nucleotide sequence of $\nu\xi$ and IS1D isolated by the S₁ nuclease technique and by cloning into pBR322. The strategy used for sequencing is shown in Fig. 2. Sequencing the ends of the fragments purified using S₁ nuclease presented some difficulty, because the 5' ends were found to be heterogeneous

(see Fig. 1C and its legend). Figure 3A shows the entire nucleotide sequence of $\nu\xi$ purified by the S_1 nuclease technique. The nucleotide sequence of the cloned copy of $\nu\xi$ gave the same result, suggesting that the repeated sequences of this kind in the Sh. dysenteriae chromosome are homogeneous. Although the cleavage map of the $\nu\xi$ sequence was completely different from that of IS1R (and IS1D), the nucleotide sequence of $\nu\xi$ showed 55% homology with that of IS1R as represented in Fig. 3A. We also found that a 31-base sequence at the ν end of the $\nu\xi$ sequence appeared in an inverted orientation at the ξ end, although there are 6 base mismatches between them. Small inverted repeat sequences are also present in IS1 $R^{1.8-10}$ and are quite homologous to those at the ends of $\nu \xi$.

When the $\nu\xi$ and IS1R sequences were searched for possible coding frames, two common frames, which we call insA and insB, were present (Fig. 4). They code for polypeptides of very similar size (InsA, $M_r \sim 10,000$, and InsB, $\sim 15,000$) and their amino acid sequences are remarkably similar (see boxed region in Fig. 3A). If pairs of related amino acids (for example, Arg-Lys) are considered to be equal, the two polypeptides from $\nu\xi$ show about 56% homology to those from IS1R.

The nucleotide sequence analysis of IS1D showed only 10 base pair changes between IS1R and IS1D. As shown in Fig. 3C, only two of these substitutions in insA and one in insB cause amino acid changes.

It has been reported that the nucleotide sequence of an IS1 present in the E. coli K-12 chromosome shows seven base pair changes when compared with that of IS1R8. In this IS1, which we refer to as IS1K, one of the base changes causes an amino acid change in polypeptide InsA, another changes an amino acid in InsB (Fig. 3C).

We postulate that the two coding frames, insA and insB, and the inverted repeat sequences seen at the ends of the $\nu\xi$ and IS1D sequences are necessary for translocation of IS1 and its iso-insertion sequences. In fact, genetic studies in our laboratory show that deletion mutations in either of these two coding frames or in the two ends of IS1R cause loss of translocation activity 11,12

In the region preceding the insA coding frame, but not the insB coding frame, we identified both a ribosome binding (Shine-Dalgarno) sequence¹³ (nucleotides 47-51 in $\nu\xi$ and 45-50 in IS1R) and a -10 homology region (or Pribnow box)^{14,15} (nucleotides 31-37 in $\nu\xi$ and 30-36 in IS1R) as indicated in Fig. 3A. This suggests that the insA message is probably transcribed and translated efficiently. On the other hand, the lack of obvious promoter sequence in the region preceding insB suggests either that insB may be transcribed very inefficiently or that it is transcribed as a part of a polycistronic message beginning at the insA promoter. The fact that the region preceding insB also lacks a Shine-Dalgarno sequence may suggest, however, that insB is very poorly translated even when the polycistronic message is transcribed efficiently. The presumed inefficient translation of InsB may be related to control of the rate at which IS1 multiplies in the chromosome.

The nucleotide sequences of unique chromosomal DNA adjacent to both ends of the $\nu \xi$ sequence and IS 1D in the cloned fragments are shown in Fig. 3B and D. Although it is generally accepted that insertion sequences and transposable elements generate directly repeated duplications of several bases at the target site on translocation (for review see ref. 2), no such direct repeat sequences are present at the junctions of $\nu \xi$ and IS1D.

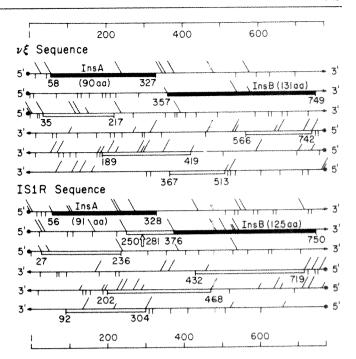

Fig. 4 The possible initiation and termination codons formed within v & and ISIR. All three reading frames of both strands were analysed as shown. Long angled lines represent AUG start codons; short-angled lines represent GUG start codons. Vertical lines indicate the presence of a UGA, UAA or UAG termination codon. All open frames for possible polypeptides are indicated in positions with numbers (see Fig. 3). The two open frames common in the two sequences are labelled InsA and InsB as shown. Note that the base change in ISID at position 281 (which eliminates a HaeIII site present in IS1R) introduces a termination codon into an open frame which precedes insB of IS1R (see open arrow), indicating that the open frame from 250 to 376 is not essential for translocation of IS1R or IS1D.

The absence of direct repeat sequences could be explained in two ways. First, deletions which occurred at the precise ends of the insertion sequences after the translocation of these sequences would result in loss of the part of the chromosome that includes the duplicated sequence. Alternatively, two copies of these repeated sequences flanking a unique chromosomal sequence could become a transposable element [as has been observed for transposable elements such as Tn9 and Tn1681 (refs 16-18)] and move into other sites on the chromosome. In these cases, the individual IS1 components of the transposable element are not flanked by direct repeats 1,19

IS1 is not thought to be essential for the survival of bacterial cells. Nevertheless, it can multiply within a bacterial host, resulting in large numbers of IS1 sequences within the host chromosome. Also, the various types of base changes that we have observed in iso-insertion sequences suggest that IS1 can evolve independently within a bacterial cell. In this respect, IS1 may be an intracellular parasite even more primitive than bacteriophages or bacterial plasmids.

We thank T. Ando for providing a large quantity of S₁ nuclease, K. Armstrong and M. McCormick for critical reading of the original manuscript, D. Davison for help with manuscript preparation, and S. Donaldson for typing of the manuscript. This work was supported by USPHS grants GM26779 to H.O. and GM22007 to E.O. and partially by support from NIH training grant CA09176.

Non-parallel evolution of metabolic and growth-promoting functions of insulin

George L. King & C. Ronald Kahn

Section on Cellular and Molecular Physiology, Diabetes Branch, NIAMDD, National Institutes of Health; Bethesda, Maryland 20205, USA

Insulin has both metabolic and growth-promoting activities¹⁻³. From extensive studies on the relative potencies of naturally occurring and chemically modified insulins, a region of the insulin molecule that is essential for its metabolic effects has been proposed⁴. Here, we have compared the effects of 23 different insulins and insulin analogues on growth (thymidine incorporation into DNA) and metabolic activities (glucose oxidation). For many insulins striking differences in potency in these two assays were observed. Most exhibited greater relative activity in growth-promoting than in the metabolic assay, suggesting that growth and metabolic activities of the insulin molecule have evolved in a non-parallel fashion and may involve separate functional domains of the molecule.

Insulin effects at the cellular level are diverse. Exposure of cells to low concentrations of insulin results in a rapid stimulation of a variety of enzymes and transport systems involved in cellular metabolism⁵⁻⁷. At higher concentrations and after longer times, insulin also exerts growth-promoting effects with stimulation of macromolecular synthesis^{3,8,9}. Using antibodies to the insulin receptor, we have recently shown that the metabolic activity of insulin is mediated by the insulin receptor, whereas the growth-promoting effects are probably mediated through one of the receptors for the insulin-like growth factors (IGFs)10. The latter are a family of polypeptides that are structurally homologous to insulin and share many common biological activities, but are immunologically distinct9. The IGFs include IGF-I, IGF-II, somatomedins A and C and multiplication stimulating activity (MSA). In addition, IGFs have their own cell-surface receptors⁹⁻¹². Whereas the biologically active site of insulin for metabolic activity and insulin receptor binding has been extensively mapped^{4,13}, little information exists on the structural requirements for its growth-promoting activity. To this end we have compared the effects of a wide variety of insulins and IGFs in two bioassays.

Dose-response curves of insulins for stimulation of glucose oxidation in dispersed rat epididymal adipocytes demonstrated the wide range of potencies of insulin analogues for metabolic effects (Fig. 1a). For turkey, pork and bonito insulins, proinsulin and desoctapeptide insulin, the relative potencies (%) in this assay were 240, 100, 42, 2 and 0.4, respectively. In contrast, dose-response curves for the stimulation of thymidine incorporation into DNA of cultured human fibroblasts by these same analogues showed both different relative potencies and a

Stimulation of glucose oxidation was measured in dispersed epididymal adipocytes of Sprague–Dawley rats (100–140 g) as the conversion of $^{14}\mathrm{C}$ -glucose to $^{14}\mathrm{CO}_2$ as described by Rodbell et al. 5 . For measuring incorporation of $^3\mathrm{H}$ -thymidine into DNA of cultured human fibroblasts 8 , cells used were from the 5th to 15th passages. After each passage, the cells were allowed to reach confluency with media containing 20% fetal bovine serum (Flow Labs 29101420), then maintained in serum-free Eagle's minimal essential media for an additional 5–7 days before use. The results shown are the average of quadruplicate assays. A control dose–response curve with porcine insulin was done with each experiment. Inter- and intra-assay variations were less than 25% and 20%, respectively.

 $^*\mathrm{ED}_{50}$ values for the hystricomorphs were derived by taking the concentration of insulin needed to stimulate thymidine incorporation that corresponds to the half-maximum of pork insulin's dose-response curve.

different order (Fig. 1b). Turkey (350%) and bonito insulins (160%) were more potent than pork insulin. Porcine proinsulin and desoctapeptide insulin remained less potent than pork insulin, but both were considerably more potent in the thymidine incorporation assay than in glucose oxidation. These differences in potency were not due to a change in the rate of degradation (data not shown). Furthermore, the differences are unlikely to be due to contamination with IGFs, because fully

[Insulin] (ng ml-1)

The divergence between insulin's metabolic and growth effects is further substantiated by data with other insulin analogues (Table 1). With the exception of hagfish insulin, all the naturally occurring insulins were at least 50% as active as pork insulin in the thymidine incorporation assay, suggesting that insulin's growth effects have withstood evolutionary changes in the molecule better than its metabolic effects. This observation is strengthened by the results with chemically modified insulins which have retained their growth activity to a greater degree than their potencies in glucose oxidation.

The most extreme examples of divergence in the two assays are shown by IGF-I, IGF-II and MSA (Fig. 2a, b). All these growth factors have <1% of pork insulin's metabolic potential, with insulin » IGF-II > MSA > IGF-I. However, when comparing their growth potentials, the order of potencies is completely reversed, with IGF-I being the most potent and insulin the least.

At high concentrations almost all the insulins and IGFs produced the same maximal response in the bioassays. Furthermore, insulin's growth effect on the human fibroblast was not additive to that of the IGFs (ref. 11 and data not shown), suggesting that these peptides have a common rate limiting step either at the receptor or beyond.

However, insulins from the family of mammals referred to as hystricomorphs (guinea pig, porcupine, coypu and casiragua) did not conform to this finding. These insulins differ from other mammalian insulins in that they are unable to bind zinc, and exhibit low degrees of dimerization and low potency for metabolic effects 4.15.16 (Fig. 2c). In contrast, when these insulins were studied in the thymidine incorporation assay, two points of interest emerged (Fig. 2d). First, like many other insulins, at low concentrations the hystricomorph insulins exhibited a greater relative potency in the growth assay than in their metabolic effects. More importantly, at higher concentrations these insulins stimulated thymidine incorporation into DNA to a greater maximum than any other insulin, insulin-like growth factors or combination of the two tested (Fig. 2d). In fact, at high concentrations guinea pig insulin approached the activity of

20% fetal calf serum, the most potent stimulus known in this assay.

10

From these data, some of the properties of the insulin molecule that are responsible for growth can be deduced. First, the growth-promoting action of insulin can tolerate a greater change in structure than the metabolic effects. Specific substitution of histidine in the A8 (A chain, residue 8) residue of insulin (for example, turkey insulin) enhances both its metabolic¹⁷ and growth effects. The B22-B30 region of insulin, which is vital for insulin's metabolic activities4, is not crucial for insulin growth effects. This is clearly demonstrated by the results of desoctapeptide insulin, and is consistent with the model for the structure of insulin-like growth factor I proposed by Blundell et al. 18 in which this portion of the molecule is covered. Finally, the unexpected finding that the hystricomorph insulins gave a higher maximum response than other insulins in the growth-promoting assay raises the possibility that they are closer functionally and evolutionarily to the IGFs than other mammalian insulins. Four areas of similarities between the sequences of hystricomorph insulins and IGFs may be important: B10 (Asn, Gln and Glu in the hystricomorphs and IGF; His in other insulins), B13 (Asp in IGF and hystricomorphs; Glu in others), B26 (Tyr in coypu, casiragua and IGFs, Phe in others) and A4 (Asp in hystricomorphs, Glu in others).

The present data thus indicate that the growth-promoting activity of the insulin molecule is distinct from its metabolic activity and is less affected by amino acid substitutions. Presumably, this reflects differences in the specificity of the receptors for the IGFs and insulin. The insulins from the hystricomorph family seem to be unique in their ability to stimulate DNA synthesis. Preliminary studies in our laboratory suggest that this superagonist property can be explained by a receptor which uniquely recognizes the hystricomorph insulins, indicating that the hystricomorph insulins may represent another class of 'insulin-like growth factors'.

We thank Drs W. Rittel (human synthetic insulin), R. Chance (beef proinsulin, bonito fish, desoctapeptide and des-Ala des Asp insulins), J. Pitts (turkey insulin), S. Emdin (hagfish insulin), R. Horuk (coypu and casiragua insulins), W. J. Neville (porcupine insulin), D. Brandenburg (des-Gly Al des-Phe B1,

butoxycarbonyl A1, and A1-B29 adipoyl insulins), R. E. Humbel (IGF-I and IGF-II), and M. M. Rechler and S. P. Nissley (MSA) for various insulins noted in Table 1. All other insulins were from Novo. We also thank Dr Jesse Roth for his guidance, Dr T. B. Blundell for suggestions in the project and Mrs Nancy Conley for secretarial assistance.

It is generally assumed that the identity of the genotype explains why there is less difference between monozygotic than between dizygotic twins. But monozygotic twins are also exposed to identical non-genetic influences, which act on the common zygote until the time of separation into the two twin partners. We have studied such influences by comparing genetically identical monozygotic and dizygotic mouse twins transplanted into foster mothers at the 8-cell stage. We show that monozygotic twins have a greater degree of similarity than genetically identical dizygotic twins. This suggests that the differences between dizygotic twins may be due in part to non-genetic influences on the zygote as far as the third cleavage stage.

Differences between monozygotic (MZ) twins derived from a single zygote of an inbred line were compared with differences between dizygotic (DZ) twins from two ova of one mother of the same line. Body weight and onset of signs of somatic maturation (first appearance of hair, eye and ear opening) were determined. The high degree of isogenicity of inbred mice has been discussed elsewhere 1-4. Our experiments were carried out on inbred AKR/NHan mice derived from brother-sister mating over more than 150 generations. Isogenicity in these inbred strains was continuously verified by testing different immunogenic and biochemical genetic markers, and by measuring morphometrical traits of the mandibula. Over 100 gene loci have been tested by the breeding units at Zentralinstitut für Versuchstiere, FRG; the results have been reported elsewhere4.

MZ twins were produced as follows: ova were collected by flushing the tuba uteri on day $3\frac{1}{2}$ post coitum (p.c.) (vaginal plug = day 1) after spontaneous ovulation. The flushing fluid⁵ contained phosphate-buffered saline (PBS) supplemented with 20% heat-inactivated (30 min at 56 °C) fetal calf serum (FCS). The zona pellucida was removed by incubation with 0.5% pronase⁶ and the denuded ova were cultured in the flushing medium at 37 °C for 3 h in an atmosphere of 95% air, 5% CO₂ (refs 7, 8). The 8-cell stages, in a microdrop of the flushing medium, were mechanically separated under liquid paraffin using an extended glass capillary tube, and both halves were incubated for 3 h as described above. The two halves, together with five to seven denuded 8-cell stages of C57BL/6JHan were then transferred to the uterus of $2\frac{1}{2}$ -day pseudopregnant, uniparous C57BL/6JHan recipients^{6,9}. DZ twins were produced in the same way except that, instead of two halves of one 8-cellstage zygote, two undivided, denuded 8-cell-stage zygotes derived from one mother were transferred.

Animals were born at \sim day 20 p.c. The litters of 4–8 offspring each were suckled by their uterine foster mothers, weaned at 25 days of age, and the males and females of each litter placed in separate cages. All animals were examined daily for health and signs of maturation, and weighed every 10 days from 31 to 101 days old. MZ and DZ AKR twins were identified by their white hair among their black C57BL/6JHan littermates. In ~200 transfer experiments, 10 litters had living MZ twins. In the same period, 13 pairs of DZ twins were produced in ~50 attempts. For each of the measured characteristics mean and standard deviation, and 'within pairs' (MS_w) and 'between pairs' (MS_b) mean squares were calculated. Analysis of variance model II (ref. 10) was used to calculate the component of variance (s_b^2) for the variation between the pairs in each group of MZ and DZ. that of male and female twin pairs separately, using the formula: $s_b^2 = 0.5$ (MS_b-MS_w). A typical calculation is given in Table 1.

Mean ± s.d., MS_w and the between pairs component of variance (s_b²) estimated in groups of MZ and DZ twins for the day of first appearance of hair, and eye and ear opening of male and females combined, and for the body weights (g) of males and females of different age. Numbers in parentheses are number of animals. NS, not significant.

Means are significantly different (P < 0.05).

The F-test was used to compare s_b² and MS_w between the MZ and DZ twin groups; the results are shown in Table 2. The mean age at first appearance of hair and of eye and ear openings did not differ (P>0.5) between MZ and DZ groups. In addition, the mean body weights of MZ and DZ did not differ (P > 0.1) in 15 out of 16 measurements made between 31 and 101 days old. The mice stopped growing at ~70 days old; the mean body weight at 81, 91 and 101 days remained constant, therefore the results of these ages were combined.

A comparison of the total variance between MZ and DZ with respect to the measured characteristics reveals no detectable trend. MS_w and s_b² for the pairs of twins are significantly different in the two groups (see Table 2, columns 4-8). In monozygotic twins MS, is extremely small, most of the variance being due to s_b^2 . In dizygotic twins MS_w was greater than s_b^2 for 9 of the 13 measurements. MS, for the monozygotic twins was significantly smaller than that of the dizygotic twins, for the observed ages of maturation and body weights in males and females up to the time of maturation (61 days). This difference remained significant in males even after maturation, but it disappeared in adult females. From repeated weight estimation for each MZ and DZ adult male at 81, 91 and 101 days of age the intra-individual component of variance was calculated to be 2.392 g. This component of variance is approximately equal to the MS, of the MZ but is smaller (P < 0.05) than that in DZ.

Thus in spite of the fact that both MZ and DZ were isogeneic and developed in identical pre- and postnatal environments, the MZ pairs showed fewer differences than the DZ pairs. A possible explanation for these findings is residual heterozygosity in the AKR inbred strain, but there is no support for such a hypothesis. We are following a divergent breeding programme in our AKR/NHan strain that is selective for the characteristics under study, to provide further evidence for the homogeneity of the gene loci involved. An alternative explanation for the larger differences observed in the DZ twins is that experimental manipulation differed between the MZ and DZ groups; whereas the 8-cell embryos of the MZ group were divided, those of the DZ group were not. However, it is difficult to see how experimental manipulation of this kind could create greater similarity. To investigate this further, control studies are being done in which, for example, two embryos at the 8-cell stage are divided and one 4-cell entity from each is transferred to a common foster mother.

From the available evidence, we conclude that each zygote is modified by a non-genetic mechanism before the third cell division in such a way that postnatal maturation times and body weights and possibly other characteristics are considerably different between individuals. If a zygote is divided after the third cell division, the modification is decisive for both monozygotic partners in the same way. It has long been known that there is a non-genetical component of variance of many quantitative characteristics which could not be accounted for by environmental influence, that is, by circumstances external to the individual. This component was called 'intangible variance'11,12 and was attributed also to 'accidents' of development. We believe that the quantitative component of variance described here is a manifestation of such intangible variance.

Population genetics of selfish DNA

Tomoko Ohta

National Institute of Genetics, Mishima, 411, Japan

Selfish DNA, which contains no genetic information but which is perpetuated in eukaryote genomes, has attracted much attention recently¹⁻⁴. Two classes of selfish DNA have been distinguished: tandemly repetitive sequences such as satellite DNA and dispersed repeated families. Unequal crossing-over is considered to be mainly responsible for spreading of the former, and an integration mechanism (as in bacterial transposons) for evolution of the latter. Here I derive equations and simulate distributions (using randomly generated numbers as data) to show how the numbers of tandem and dispersed repeat units of selfish DNA in a population change with time. I find that whereas the mean number of clustered and dispersed units remains constant, the distribution becomes increasingly dispersed with time.

Both unequal crossing-over and integration occur randomly, such that the overall mean change of unit number is zero. I assume that the number of units per genome in an evolving population changes by inter-genome exchange as well as by random sampling drift at reproduction. How does the mean number of units per genome of the population drift with time? In the previous study⁵, the relationship between the mean and variance of the number of units in the population was obtained when the above processes balance each other. I shall start from such an equilibrium situation. The basic premise of this study is that self-replication has a more profound effect on the evolution of selfish DNA than individual base substitution, on which evolution of ordinary stable gene loci depends.

The same model as in ref. 5 is used; however, the tandem and the dispersed repeated sequences are here treated separately. Each repeating unit of the dispersed class is assumed to have a constant probability α_1 of either forming an additional copy of itself or being deleted in one generation. Exchange of units between the genomes also takes place in each generation at rate β . At meiosis, the units are assumed to be randomly distributed to the two daughter cells by the normal methods of chromosomal segregation. Both unequal sister-chromatid exchange (rate per generation α_2) and unequal interchromosomal crossing-over change the amount of clustered selfish DNA. It is assumed that the mean number of duplicated or deleted units in one generation is proportional to n, the number of repeating units in a genome (constant of proportionality, a). Inter-chromosomal crossing-over between the homologous repeated DNA is complicated because the two genomes usually have different numbers of repeating units. Recombination can be either 'equal' or 'skewed' depending on where the smaller segment of repeated DNA comes in relation to the larger segment. Equal recombination occurs when the small segment falls completely within the larger segment, and skewed recombination when it does not. The equal recombination rate per generation is denoted by β_I and the skewed one, by β_1 . In addition to the above processes, random sampling of gametes occurs at reproduction (number of breeding individuals, N). The parameters of various processes for the two classes are summarized in Table 1.

Let x and y be the average number of units per genome in the populations of tandem and the dispersed repeated sequences respectively. They are random variables and, in the following, their distribution is investigated as function of time. In numerical experiments I generate data starting off with random numbers, and study the distribution obtained using the equations derived below.

The 'pseudosampling (PSV)' method of Kimura⁶ is used, which greatly facilitates the simulation. If x is the average number of units in the present population, then its number in the next generation, x', is given by

$$x' = x + \xi_{psv'} \tag{1}$$

where $\xi_{\rm psv}$ is a uniform random number with mean 0 and the variance expected after the occurrence of the various processes given in Table 1. The variance $(V_{\Delta x})$ of change of x $(\xi_{\rm psv})$ may be calculated using equations (5) and (12)–(14) of ref. 5, and by noting that x is the average of 2N variables. Note further that each genome undergoes, independently of the other, replication and exchange processes, before it is sampled for the next generation. Also, equation (13) of ref. 5 is equivalent to stating that the square of the average number of units increases by the absolute value of the right term of this equation by sampling of gametes. It becomes

$$V_{\Delta x} = \frac{x^2}{2N} \left(\alpha_2 a^2 + \frac{\beta_1'}{6} \right) \left\{ 1 + \frac{6(\alpha_2 a^2 + 1) - 2\beta_1 - \beta_1'}{2\beta_1 + \beta_1' + 3N^{-1} - 6\alpha_2 a^2} \right\}$$
 (2)

by assuming that $2\beta_1 + \beta_1' + 3N^{-1} > 6\alpha_2 a^2$. The simulation is continued, starting from a given value of x at time 0, for 50N generations, and it is repeated 1,000 times. Whenever x becomes <1/N, x is put to 0, and the population has lost the

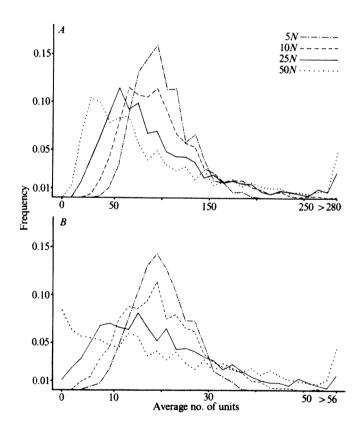

Fig. 1 A, results of simulations of the distribution of the average number of tandemly repeated units per genome in the population. Parameters are: initial number of units $(x_0) = 10^2$; unequal crossover rate $(\alpha_2) = 10^{-2}$; fraction of units duplicated or deleted (a) = 0.1; equal recombination rate $(\beta_1) = 10^{-2}$; skewed recombination rate $(\beta_1') = 10^{-3}$; and $N = 10^4$. Distribution was obtained for the intervals of 10 units, with terminal classes of 0 and >280 units. B, results of simulations for the dispersed repeating sequences. Parameters are: initial number of units $(y_0) = 20$; rate of duplication or deletion of each unit $(\alpha_1) = 10^{-2}$; rate of inter-genome exchange $(\beta) = 1$; and $N = 10^2$. The product, $N\alpha_1$, is chosen to be reasonably realistic. Distributions are for the intervals of 2 units with terminal classes of 0 units and >56 units. The distributions for t = 5N, 10N, 25N and 50N generations are given. They are the result of 1,000 independent trials.

Table 1 Processes responsible for the evolution of selfish DNA and the parameters used

	•	
Processes	Tandemly repeated sequences (x)	Dispersed repeated sequences (y)
Replication process	Unequal crossing-over by sister-chromatid exchange α_2 = rate per cluster per generation a = mean fraction of duplicated or deleted units at an unequal crossing-over in one cluster of repeated sequence	Integration mechanism α_1 = rate in one generation at which each unit is either duplicated or deleted independently
Inter-genome exchange process	Inter-chromosomal recombination at meiosis β_1 = rate of recombination in one generation which takes place in this sequence when the pairing of two chromosomes is equal β_1 = the above rate when the pairing of two chromosomes is skewed	Random distribution to the daughter cells at meiosis β = rate per generation at which the dispersed units are distributed
Random genetic drift	N = effective population size	N = effective population size

repeating sequence. In practice, ξ_{psv} may be obtained by choosing a random number rnd (uniformly distributed between 0 and 1) such that

$$\xi_{\text{psv}} = \sqrt{3V_{\Delta x}} (2rnd - 1) \tag{3}$$

(See ref. 6.)

The distribution of y (the mean number of units of the dispersed family) is similarly studied by using $y' = y + \xi_{psv}$. ξ_{psv} now follows a uniform distribution with mean 0 and variance that equals the variance of the change of y after the occurrence of the three processes of Table 1. The variance takes the following form from equations (3), (8), (13) and (14) of ref. 5:

$$V_{\Delta y} = \frac{y}{2N} \left(\alpha_1 + \frac{N \alpha_1 \beta}{1 + 2N \alpha_1} \right) \left(1 + \frac{2 - \beta}{\beta + N^{-1}} \right)$$
 (4)

From equations (2) and (4), it is possible to approximate the variance of x or y at any time, that is, the variance of the number of units among the isolated populations. They may be expressed as

$$V_{x,t} = V_{\Delta x_0} t \tag{5}$$

and

$$V_{\mathbf{y},t} = V_{\Delta \mathbf{y},0}t \tag{6}$$

where t denotes the tth generation after splitting of the populations, and $V_{\Delta x_0}$ and $V_{\Delta y_0}$ are obtained by replacing x of equation (2) with x_0 , and y of equation (4) with y_0 respectively, where x_0 and y_0 are the numbers of units of clustered and dispersed classes at t = 0. As β (in equation (4)) is likely to be unity in sexually reproducing species (because the rate at which the dispersed family is divided into the daughter cells at meiosis is unity), the product $N\alpha_1$ is the most crucial factor in determining the distribution of dispersed families.

Figure 1A,B shows the results of simulation. The values of the parameters used are not known exactly in real cases and are tentative suggestions. Note that several dispersed families are known in which the number of units per genome is of the order

Table 2 Comparison of the observed and expected variances of the average number of units per genome among the isolated populations

Time in	Tandemly	repeated	Dispersed	repeated
generations $(\times N)$	Observed variance	Expected variance	Observed variance	Éxpected variance
5	768	798	32.9	34.2

40	8,568	6,381	274.8	273.3
45	8,852	7,178	300.3	307.5
50	9,484	7,976	320.8	341.6

of 10 (refs 7-10) and that the parameters α_1 and N are chosen such that the product, $N\alpha_1$, is a realistic value (= 1). For the clustered families, reasonable values are also chosen11-14, except for N, which is too small but makes the simulation easier because of more rapid differentiation. The figure shows, starting from the initial number of units, how the distribution of x or y changes with time. For example, after 10N generations, the value of x ranges from 30 to 290 with the peak at about $x_0 = 100$, and y, from 3 to 53, with the peak at $y_0 = 20$. As t increases, the distribution becomes more and more dispersed in both classes. Nevertheless, the overall mean of 1,000 replicated lines stays constant; at the 50N th generation, $\bar{x} = 98.1$ and $\bar{y} = 19.9$. Such an outcome would be characteristic of random processes of this kind. Note that, at this generation, ~8% of 1,000 lines have lost the dispersed repeating sequence, and about the same proportion contained less than 20 copies of the clustered class. Such a proportion would increase with time even if the overall mean remained unchanged.

The variances of x and y have also been calculated and compared with the theoretical predictions from equations (5) and (6), as shown in Table 2. The agreement between the theoretical and simulated results is generally satisfactory; however, for the clustered families, equation (5) underestimates the true value when t gets large. This is because the number of units duplicating or being deleted is assumed to be proportional to the number of units, and therefore the variance of the change of x is proportional to x^2 , the expectation of which becomes larger than x_0^2 as t gets large.

It has been shown that whereas some species have the same α satellite DNA15, other closely related species have lost the sequence 16,17. It has thus been argued that this sequence may be important in speciation¹⁶. However, as can be seen from the present results, spreading and loss of repeated sequences occur randomly and it is extremely difficult to draw any conclusion from such an observation. Data on species comparisons of dispersed repeated sequences are also rapidly accumulating (see ref. 7 for review). Most examples seem to fit in with the framework of the present theory

I thank Dr M. Kimura for many useful suggestions on the manuscript.

Inhibition of actin polymerization in blood platelets by cytochalasins

Joan E. B. Fox & David R. Phillips

Department of Biochemistry, St Jude Children's Research Hospital, Memphis, Tennessee 38101, USA

It has been suggested that the polymerization of actin to form actin filaments is critical for many functions in non-muscle cells including phagocytosis, cell division, secretion and cell motility1,2. In support of this suggestion, many of these functions are inhibited by cytochalasins3 which also inhibit the actin nucleiinduced polymerization of purified actin⁴⁻⁷. Recent studies suggest that the cytochalasins (cytochalasins B, D and E) inhibit polymerization by binding to the growing end of actin filaments and blocking the further addition of monomeric actin molecules^{4,7-9}. If the cytochalasins inhibit cellular contractile functions by a similar mechanism, they could be useful tools in determining whether actin polymerization is required for specific processes within cells. Blood platelets provide an excellent system for testing this as exposure of platelets to thrombin results in a rapid polymerization of actin^{10,11}. We have now studied the effects of the cytochalasins on thrombininduced actin polymerization and report here the first clear evidence that cytochalasins inhibit actin polymerization in intact

The filamentous actin content of platelet samples was determined in platelet lysates by the method of Blikstad *et al.*¹² who showed that nonfilamentous actin inhibits DNase I activity while filamentous actin has little effect unless depolymerized by guanidine hydrochloride. Platelets were lysed by adding an equal volume of Triton extraction buffer (2% Triton X-100 (v/v), 10 mM EDTA, 100 mM Tris-HCl, pH 7.4). This buffer, unlike that used elsewhere ^{10,12}, did not depolymerize actin filaments, so that identical inhibitory values were obtained whether the assay was performed 30 s or 2 h after lysis (J.E.B.F., M. E. Dockter & D.R.P., in preparation).

In Triton lysates from unstimulated platelets, the DNase I inhibitory activity in the absence of guanidine hydrochloride was ~50% of that in its presence. When platelets were activated with thrombin before the addition of Triton X-100, the amount of guanidine hydrochloride-dependent DNase I inhibitory activity increased to ~70% of the total. This stimulus-induced transformation was rapid and was almost complete within 15 s (Fig. 1). We conclude that $\sim 50\%$ of the total actin was in a filamentous form in unstimulated platelets and that this increased to $\sim 70\%$ on thrombin activation. In support of this conclusion, we found that only the guanidine hydrochloridedependent inhibitory activity was sedimented by centrifugation of lysates at 100,000 g for 3 h. Furthermore, sedimented material contained structures morphologically similar to actin filaments¹³. Finally, quantitation of actin in sediments and supernatants by densitometry of Coomassie blue-stained gels after SDS-polyacrylamide gel electrophoresis gave actin contents that were within 5% of those obtained by the DNase I inhibition assay. Thus, the amount of inhibition of DNase I activity in Triton lysates correlates directly with the amount of nonfilamentous actin (an assumption used throughout this study), and the amount of filamentous actin within platelets rapidly increases after exposure to thrombin.

Figure 1 shows that 10^{-6} M cytochalasin E added 100 min before thrombin inhibited the thrombin-induced increase in actin filament content. Cytochalasins D and B had similar effects. None of these cytochalasins had any effect when added

simultaneously with the Triton extraction buffer. As shown in Table 1, the inhibitory effect was rapid, as the same extent of inhibition was observed whether cytochalasin D was present for 100 min or for only 1 min before the addition of thrombin. Cytochalasin D did not affect the filament content in unstimulated platelets (Table 1). These data show that the decreased filament content in thrombin-treated platelets is due to an inhibition of thrombin-induced actin polymerization and not to

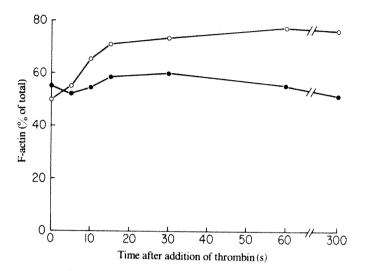

Fig. 1 Inhibition of thrombin-induced actin polymerization in human platelets by cytochalasin E. Human platelets from freshly drawn blood were washed as previously described²⁴ and suspended to a concentration of 2×10^8 per ml in 138 mM sodium chloride, 2.9 mM potassium chloride, 12 mM sodium bicarbonate, 0.36 mM sodium phosphate, 5.5 mM glucose and 1 mM EDTA, pH 7.4. The platelet suspension was incubated with 0.2% (v/v) DMSO (dimethyl sulphoxide) (O) or 10^{-6} M cytochalasin E in 0.2% DMSO () at 37 °C. After 100 min, thrombin was added (final concentration 0.1 NIH U ml⁻¹) and at intervals varying from 0 to 300 s, platelets were lysed by addition of an equal volume of Triton extraction buffer and a 10-µ1 aliquot removed for determination of the amount of unpolymerized actin by the DNase inhibition assay. The total actin content in lysates was measured after depolymerization of filamentous actin by addition of an equal volume of buffer containing 1.5 M guanidine-HCl, 1.0 M sodium acetate, 1.0 mM sodium ATP, 20 mM Tris-HCl and 6 mM calcium chloride, pH 8.6 (to yield a final pH of 7.4, determined experimentally). Kinetic analyses were initiated within 30-60 s after platelet lysis. The absorbance was continually monitored by a dual-beam spectrophotometer directly linked to a Hewlett Packard 9845S computer. The linear portion of the sigmoidal curve was determined by regression analysis and runs were discarded if the correlation coefficient was less that 0.999. Duplicate determinations of the DNase I inhibitory activity from an individual platelet sample usually agreed within 5%. The actin filament content (F-actin) is expressed as a percentage of the total actin.

a decreased filament content of unstimulated platelets. Similar increases in actin polymerization were observed when platelets were stimulated for 30 s with 0.4 μ M ionophore A23187 or for 60 s with 20 μ M ADP. Cytochalasin D also inhibited these stimuli-induced increases.

Although the cytochalasins may affect many metabolic processes within cells, two sites of action that could potentially affect actin polymerization have been described: one site is on the actin filaments⁴⁻⁹; the other is on the membrane-bound glucose transport system^{14,15}. However these sites have differing affinities for the cytochalasins. The site on actin filaments has been measured using both purified actin^{4,8,9} and actin-containing membrane complexes^{5,16}. In both cases, cytochalasins D and E bound with higher affinity that cytochalasin B with the binding

affinity corresponding to the inhibition of actin nuclei-induced polymerization. In contrast, the site of the membrane-bound glucose transport system has a higher affinity for cytochalasin B than for cytochalasin D or E which, unlike cytochalasin B, do not inhibit glucose transport into cells¹⁴⁻¹⁸.

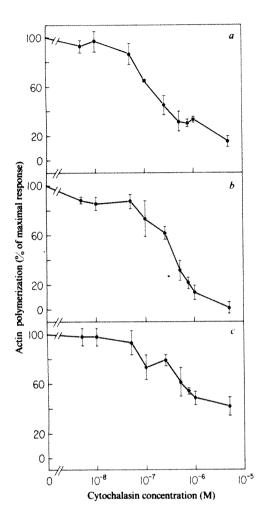

Fig. 2 Comparison of the effects of cytochalasins D(a), E(b) and B(c) on thrombin-induced actin polymerization in human platelets. Platelet suspension $(2\times10^8~{\rm per~ml}^{-1})$ was incubated at 37 °C with 0.5% ethanol (v/v) or with varying concentrations of the different cytochalasins in 0.5% ethanol. After 88 min, buffer or thrombin (final concentration 0.1 NIH U ml⁻¹) was added and 30 s later the platelets were lysed by addition of Triton extraction buffer. The actin filament content of lysates was determined as described in Fig. 1 legend and the thrombin-induced increase in actin filaments expressed as a percentage of the increase obtained when thrombin was added to platelets that had not been exposed to cytochalasin. Values shown are the mean \pm s.e.m: from four donors.

Figure 2 compares the effects of the three cytochalasins on thrombin-induced actin polymerization. At 5×10^{-6} M, cytochalasins D and E decreased the thrombin-induced actin polymerization by $\sim 85\%$ and 100%, respectively, while cytochalasin B inhibited polymerization by only $\sim 60\%$. Within the limits of experimental error, the concentrations of cytochalasins D and E required to produce half-maximal inhibition of polymerization were indistinguishable ($\sim 2\times 10^{-7}$ M) and were lower than the concentration of cytochalasin B required for a similar inhibition ($\sim 10^{-6}$ M). These concentrations are similar to those that bind to actin filaments and inhibit actin polymerization in purified systems 4.7.9. The relative order of potency

Table 1 Effect of time of preincubation of platelets with cytochalasin D on the actin filament content of unstimulated and thrombin-activated platelets

		Filan	nentous	actin	(% of t	otal)	
Addition during	Stimulatory	Time of preincubation					
preincubation	agent	1	5	20	70	100	
Ethanol	None	52.1	51.6	48.1	48.2	50.5	
	Thrombin	69.5	65.2	60.6	66.2	67.3	
Cytochalasin D in ethanol	None	49.7	49.1	47.2	48.1	50.1	
	Thrombin	54.4	56.1	51.6	55.4	56.3	

Platelet suspensions were incubated with 0.5% ethanol (v/v) or with 2.5×10^{-5} M cytochalasin D in 0.5% ethanol at 37 °C. At intervals from 1 to 100 min, buffer or thrombin was added and after 30 s, platelets were lysed with Triton extraction buffer and the actin filament content measured as described in Fig. 1 legend. Values given are the actin filament content as a percentage of the total platelet actin.

agrees with the notion that the cytochalasins inhibit actin polymerization by binding to preformed actin filaments and is inconsistent with a mechanism involving inhibition of glucose transport. In support of this view, the inhibitory effect of cytochalasin was rapid (Table 1), a result not expected if the drug inhibited glucose transport sites alone. In addition, concentrations of cytochalasin that completely inhibited thrombin-induced actin polymerization had no effect on the thrombin-induced phosphorylation of two platelet polypeptides¹⁹ or on the thrombin-induced association of myosin with platelet cytoskeletons¹³.

It has been proposed that actin filaments 'treadmill' where one end is a net polymerizing end and the other a net depolymerizing end^{20,25}. Experiments showing that the cytochalasins decrease the lengths of preformed actin filaments, unless the net depolymerizing ends are blocked, have been interpreted as evidence for such a mechanism8. If the cytochalasins inhibit thrombin-induced actin polymerization by binding to actin filaments, they must have access to the filaments before stimulation. Although the permeability of platelet plasma membranes to the cytochalasins has not been verified experimentally, we predict from their structure that they would readily cross plasma membranes. However, our results show that the cytochalasins had no measurable effect on the filament content when incubated for up to 100 min with unstimulated platelets (Table 1). This suggests that if 'treadmilling' occurs in unstimulated platelets, it occurs too slowly to be detected in the times used here, possibly because the depolymerizing ends are blocked.

Recently, Morris and Tannenbaum²¹ reported that cytochalasin D did not decrease the filament content of HEp-2 cells. These authors conclude that as cytochalasin D inhibits motile functions without decreasing filament content, the inhibitory effect is not due to a limitation of the availability of filaments. However, it is becoming increasingly clear that actin polymerization can occur on cellular stimulation 10,11,22,23. Such responses need not result in a net measurable increase in filament content as occurs within platelets, but may involve small increases in filament content within specialized areas of cells. Our observations that the cytochalasins inhibit actin polymerization in platelets suggest that cytochalasins may inhibit cellular processes³ by preventing the increased formation of actin filaments required for these processes. Experiments are now being done to determine whether the concentrations of cytochalasins that inhibit actin polymerization in platelets cause corresponding inhibition of platelet responses (shape change, aggregation, release of granule contents or clot retraction), and it is anticipated that similar studies will help to determine the role of stimuli-induced actin polymerization in other nonmuscle cells.

We thank Dr Michael Dockter for writing the computer program for the DNase I inhibition assay. This work was supported by grants HL 15616, HL 21487 and Career Development Award HL 00080 (to D. R. P.) from the N. I. H. Cancer Center Support (CORE) grant CA 21765 from the NCI and ALSAC.

E. coli contains eight soluble proteolytic activities, one being ATP dependent

K. H. Sreedhara Swamy* & Alfred L. Goldberg

Department of Physiology, Harvard Medical School, 25 Shattuck Street, Boston, Massachusetts 02115, USA

Escherichia coli selectively degrades polypeptides with highly abnormal conformations¹⁻⁴. Normal cell proteins are degraded more slowly, but this process increases when the bacteria lack required nutrients^{1,5-7}. The pathways by which aberrant or normal proteins are hydrolysed are not known^{1,3,4}, but these processes require metabolic energy^{3-5,8,9}. Recently, cell-free proteolytic systems have been obtained from E. coli^{4,10} and mammalian cells^{3,11-15} that are stimulated by ATP. To clarify the pathway of intracellular protein degradation and to determine whether ATP might directly influence specific proteolytic enzymes, we have now undertaken to define the various proteases in E. coli. Our studies demonstrate the existence of eight distinct soluble proteolytic activities in E. coli extracts. Seven seem to be new enzymes. Six are serine proteases that hydrolyse ¹⁴C-globin and ³H-casein, while two others are metalloenzymes that degrade 125 I-insulin but not these larger polypeptides. One of the globin-degrading enzymes is stimulated markedly by ATP and thus may be the rate-limiting enzyme for protein breakdown in vivo.

Although several reports have concerned the isolation of proteases from E. coli, this field is in a confusing state. The so-called 'protease I' and 'protease II', which cleave chromogenic substrates for chymotrypsin and trypsin respectively^{16,17}, show little or no hydrolytic activity against proteins 18,19

Furthermore, mutants lacking them have a normal capacity to degrade cell proteins¹⁹⁻²². Another 'protease' has been purified²³ using a chromogenic substrate of subtilisin, but its ability to hydrolyse proteins has not been established. In addition, an aminopeptidase (pepN) has been purified, which has been claimed to have some endoprotease activity²⁴. An activity that can degrade casein, named 'proteaseA', has been partially purified²⁵ but it is probably not a single enzyme (see below). Cheng and Zipser²⁶ have purified an enzyme, protease III, that hydrolyses the amino-terminal fragments of β -galactosidase ('auto- α '), but it is not essential for protein degradation in vivo²⁷. Finally, these bacteria contain various peptidases that are essential for growth on peptides and hydrolyse small peptides generated during intracellular protein breakdown^{28,29}.

We therefore undertook a systematic search for protease activities in E. coli. For substrates, we used 14C-methylapohaemoglobin, ³H-methyl-α-casein and ¹²⁵I-insulin. Because insulin is a small polypeptide, it may be degraded by enzymes involved only in the later steps in the complete degradation of cell proteins^{29,30}. Extracts of E. coli K-12 hydrolysed all three substrates, but only degradation of globin was significantly stimulated by ATP. The degree of stimulation by ATP (60%) in these extracts, which were prepared with the French press from frozen cells, is smaller than the two- to threefold effects reported previously with fresh cells lysed by gentler methods 10,36

To isolate the proteolytic activities responsible, we fractionated these extracts on DEAE-cellulose and eluted the adsorbed proteins with a NaCl gradient (Fig. 1). Five different peaks with proteolytic activity were found (designated I-V, according to their order of elution). These same peaks, and no additional ones, were found in several other E. coli K-12 strains that had been freshly grown and collected at either late log or stationary phase. Of special interest was the finding that one of the peaks that degraded globin and casein (IV) was stimulated dramatically by ATP, and this is presumably the activity responsible for the stimulation of globin and casein hydrolysis by ATP in the crude extracts¹⁰

Peak I shows strong hydrolytic activity against globin and casein, but very slight activity against insulin. Peak I was further characterized by chromatography on CM-cellulose (Fig. 2) and by gel filtration on Sepharose 6B (data not shown). Both techniques resolved two distinct activities, both of which hydrolyse globin and casein. Peak IA shows on gel filtration an unusually large molecular weight (\sim 500,000), whereas IB has a molecular weight of ~82,000. Both IA and IB are sensitive to diisopropyl fluorophosphate (DFP), and thus are serine proteases.

Peak II hydrolyses insulin, globin and casein. Isoelectric focusing (Fig. 3) and CM-cellulose chromatography at pH 5.2 (data not shown) can both resolve this fraction into three proteolytic peaks, one active against insulin and the other two against globin and casein. Both globin-degrading activities, IIB and IIC, seem to be serine proteases, but they differ in their relative sensitivities to DFP as well as in their heat stabilities³¹. The insulin-degrading enzyme (IIA) resembles in many respects protease III purified by Cheng and Zipser²⁶. Like protease III, peak IIA rapidly hydrolyses amino-terminal fragments of β galactosidase (auto- α) and is sensitive to metal-chelating agents (EDTA and o-phenanthroline). Furthermore, a mutant lacking protease III (ptr), isolated by Cheng et al.27, specifically lacked the insulin-degrading activity in peak II. These findings (K.H.S.S., C. H. Cheng and A.L.G., unpublished results) indicate that the insulin-degrading activity is identical to protease II.

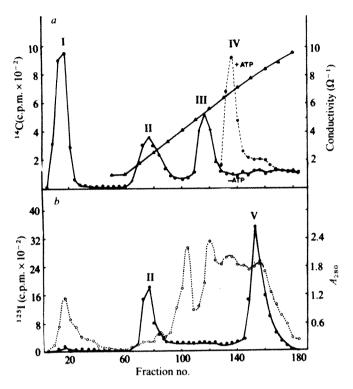

Peak III hydrolyses globin (Fig. 1) and casein but not insulin. Because it is sensitive to DFP, the enzyme also seems to be a serine protease.

Peak IV was the one ATP-stimulated activity. The stimulation of globin or casein degradation by ATP ranged from 4- to 10-fold in the various fractions and required Mg²⁺ ions. The low amount of globin hydrolysis evident in the absence of ATP decreased further on use of a narrower salt gradient or DEAE-Sepharose, which resulted in an enzyme that seemed to be

^{*}Present address: Department of Pharmacology, University of Vermont, College of Medicine, Burlington, Vermont 05405, USA

completely dependent on ATP. This enzyme showed no activity against insulin, which explains the finding that insulin hydrolysis was not stimulated by ATP in crude extracts. The ATP-stimulated activity shows the DFP-sensitivity characteristic of a serine protease.

Peak V contained insulin-degrading activity that was sensitive to o-phenanthroline but not to DFP. This peak did not digest

DEAE-cellulose chromatography of proteolytic enzymes from E. coli K-12. In a, fractions were assayed for proteolytic activity against 14C-globin in the absence (O or presence (●---●) of 3 mM ATP. In b, proteolytic activity against 125I-insulin (O--O) was assayed. Also shown in a is the conductivity (\blacktriangle — \blacktriangle) and in b, the A_{280} ($\bigcirc \cdots \bigcirc$). In all peaks except peak IV, the hydrolysis of 14 C-globin and 125 I-insulin was not stimulated by ATP (for clarity, these data were not shown). The globindegrading peaks also hydrolysed ³H-casein (data not shown). Cell-free extracts were prepared from 50 g of frozen E. coli K-12 cells (Grain Processing Co.). After thawing at 4 °C, the cells were suspended in 100 ml of 50 mM Tris-HCl, pH 7.8, 10 mM MgCl₂ and 200 mM KCl, and disrupted in a French press at 14,000 p.s.i. The homogenate was centrifuged at 30,000g for 30 min, and the supernatant centrifuged again at 130,000g for 3 h. The supernatant was dialysed overnight against 10 mM Tris-HCl, pH 7.8, containing 5 mM MgCl₂. The dialysed extract was adsorbed to a DEAE-cellulose column (2.5×27 cm) equilibrated with 10 mM Tris-HCl, pH 7.8. containing 5 mM MgCl2. The column was washed with the same buffer until the A_{280} of the eluate was <0.05. The adsorbed proteins were then eluted with 1,600 ml of a linear NaCl gradient (0-0.25 M NaCl). The flow rate was 100 ml h⁻¹ and 12-ml fractions were collected. Proteolytic activity was estimated by following the degradation of ¹⁴C-globin (2-4×10⁶ c.p.m. per mg), ³H-casein (1×10⁷ c.p.m. per mg) or ¹²⁵I-insulin (125-140 mCi per mg, Cambridge Nuclear and Radiopharmaceutical Corporation) to products soluble in 10% trichloroacetic acid. ¹⁴C-globin was prepared by methylating crystalline beef haemoglobin (Sigma) with ¹⁴C-formaldehyde (40– 60 mCi mmol⁻¹, NEN) and bovine α -casein with ³H-formaldehyde (40–60 mCi mmol⁻¹) as described previously⁴⁸. To increase its proteolytic susceptibility, haem was extracted from the haemoglobin using methyletone⁴⁹ All the assaus ware corried out in 50 methyletone. . All the assays were carried out in 50 mM Tris-HCl, pH 7.8, ethylketone 10 mM MgCl₂, in the presence or absence of 3 mM ATP. When assayed with globin or casein as a substrate, the incubation mixture contained $100-200~\mu l$ of enzyme preparation and 4–5 μg of ¹⁴C-globin or 25 μg of ³H-casein in a final volume of 0.5 ml. Assays using insulin as a substrate contained 12.5 μ g insulin (Lilly), a trace amount of ¹²⁵I-insulin (12–15,000 c.p.m.) and the enzyme preparation in a final volume of 0.5 ml. The incubations were performed for 2 h at 30 °C when globin or casein was the substrate, and for 1 h at 37 °C when insulin was the substrate. After incubation, 40 μ l of bovine serum albumin (30 mg ml⁻¹) was added as a carrier and 60 µl of 100% trichloroacetic acid to precipitate the proteins. The assay tubes were kept on ice for 30 min, and after centrifugation, 0.4 ml of acid-soluble products from ¹⁴C-globin or ³H-casein hydrolysis were counted in 4 ml of Liquiscint (National Diagnostics). The products of ¹²⁵I-insulin hydrolysis are counted in an autogamma spectrometer. The protein was determined by the method of Lowry et al. 50 using crystalline bovine serum albumin as standard.

casein or globin. No additional proteolytic activity could be eluted with higher concentrations of NaCl.

These studies and related ones demonstrate the existence of eight soluble proteolytic activities in E. coli, all of which have now been purified to near homogeneity. The complete purification and characterization of these enzymes will be reported elsewhere (refs 31-33 and K.H.S.S., C. H. Chung and A.L.G., manuscripts in preparation). Of these, the six globindegrading enzymes seem to be serine proteases. By contrast, the enzymes that degrade insulin (IIA and V) and similarly sized polypeptides are metalloproteases (Table 1). All these activities represent new enzymes31 except for the insulin-degrading enzyme (IIA), which seems to be identical to protease III26. All these activities are also found in mutant strains lacking proteases I and II and aminopeptidase N. These enzymes are also distinct from the recA gene product, which catalyses the ATP-dependent proteolytic cleavage of the \(\lambda\) repressor during prophage induction^{34,35}, but does not hydrolyse casein or globin to acidsoluble material (data not shown). Regnier and Thang25 partially purified a casein-hydrolysing activity, named protease A, which was eluted from DEAE-cellulose at the same ionic strength as peak II. This peak contains three enzymes that differ in their isoelectric points, sensitivities to inhibitors and substrate specificities (Fig. 3). Thus, protease A is a mixture of proteases, rather than a single enzyme.

The marked stimulation (4-40-fold) of peak IV protease by ATP can account for the energy requirement for protein breakdown in vivo $^{1.8,9}$. In crude extracts, a much smaller stimulation of proteolysis by ATP (60-200%) was observed 10 , probably because of the five additional globin-degrading enzymes active in the absence of ATP. Previous studies 8,30 indicate that the initial endoproteolytic steps in protein breakdown require ATP, and it is therefore likely that these steps are catalysed by the ATP-stimulated protease in peak IV. Recently, this enzyme has been shown to be the product of the lon gene (also called CapR and deg) 32,33,36,37 , and lon mutants have a reduced capacity to degrade abnormal proteins 36,37 .

When cells are disrupted by gentler methods than those used here, a large amount of ATP-stimulated proteolytic activity is associated with the cell membrane³⁰. It is not clear whether the ATP-stimulated activities in the soluble and membrane fractions are different enzymes or whether the soluble activity is

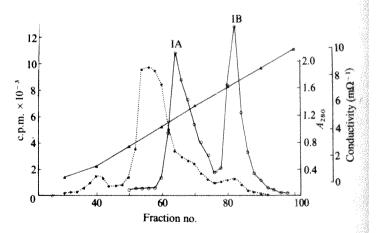

Fig. 2 CM-cellulose chromatography of proteases in peak I. Hydrolysis of ${}^3\mathrm{H}$ -casein (O——O), A_{280} (\bullet · · · • •) and conductivity (\bullet —— \bullet) are shown. The pooled fractions from peak I of the DEAE-cellulose column Fig. 1) were concentrated and dialysed against 10 mM sodium acetate buffer, $p\mathrm{H}\,5.6$. After removing the precipitated material by centrifugation, the proteins were loaded onto a CM-cellulose column (1.5 × 12 cm), equilibrated with 10 mM sodium acetate buffer, $p\mathrm{H}\,5.6$. The adsorbed proteins were eluted with 400 ml of 0–0.3 M linear NaCl gradient. The flow rate was 35 ml h⁻¹ and 4-ml fractions were collected.

released from a membrane-associated form during cell breakage. Some of the other soluble enzymes described here may also be derived from the inner or outer membranes during cell

A major task for future research will be to clarify which of these enzymes are involved in the degradation of abnormal proteins and in the breakdown of normal cell constituents in starving cells. These proteases may also have critical roles in other physiological processes, such as the processing of secretory or membrane proteins³⁸⁻⁴¹, utilization of exogenous peptides²⁸, phage morphogenesis^{28,42}, breakdown of peptides²⁸, phage morphogenesis^{28,42}, breakdown of colicins⁴³⁻⁴⁵ and inactivation of regulatory proteins^{34,42,46}. One important clue to the physiological roles of these enzymes is their subcellular distributions. Elsewhere we shall demonstrate that one of the insulin-hydrolysing activities is found in the periplasm (IIA) and one in the cytoplasm (V). One globindegrading activity (IIB) is localized in the periplasm, one (IB) seems to be distributed equally between periplasm and cytoplasm, and the others (IA, IIC, III, IV) are cytoplasmic. Presumably, these latter enzymes are involved in the catabolism of intracellular proteins.

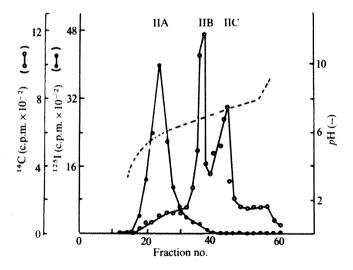

Fig. 3 Isoelectric focusing of peak II. The peak II fractions from DEAEcellulose column (see Fig. 1) were combined and concentrated by precipitating the proteins by adding solid ammonium sulphate to 95% saturation. After centrifugation at 31,000g for 30 min, the pellet was dissolved, dialysed against 1% glycine overnight and applied to the isoelectric focusing column. Isoelectric focusing was performed using a LKB 110-ml column in a sucrose gradient with 1% solution of Ampholine in the pH range 5-8. Electrofocusing was conducted for 22 h at 4 °C with a constant voltage of 1,600 V. Fractions (2 ml) were collected from the bottom. The pH of the fractions was measured at 4 °C (----) and 0.2-ml aliquots were assayed for activity against 125 I-insulin (•—•) and 14 C-globin (O——O). The peaks of IIA, IIB and IIC have isoelectric points (pI) of 5.75, 6.75 and 7.36, respectively.

The discovery of seven new enzymes necessitates the choice of a useful nomenclature. Unfortunately, the lack of precise information about their physiological functions or chemical specificities precludes informative designations. Therefore, we have decided to introduce a novel nomenclature for these enzymes. As the two metalloenzymes that degrade insulin have distinct compartmentalizations in the cell⁴⁷, we suggest the name Pi for the periplasmic insulin-degrading enzymes (IIA) and Ci for the cytoplasmic insulin-degrading enzyme (V) (Table 1). Such a scheme, based on subcellular distribution, is not useful for the enzymes that degrade globin and casein. We would like to introduce an easily remembered nomenclature for these six enzymes: proteases Do, Re, Mi, Fa, So and La in their order of elution from DEAE-cellulose and CM-cellulose or isoelectric focusing (Table 1). This nomenclature also permits an easily remembered designation for their genetic loci. When more is known about the properties or roles of these enzymes, a more descriptive nomenclature will be possible.

These studies have been supported by research grants from the Juvenile Diabetes Fund, the Kroc Foundation and the National Institutes of Neurological Disease and Stroke. We thank Ms Maureen Rush and Ms Robin Levine for assistance in the preparation of this manuscript, Drs Chin Chung and Fred Larimore for valuable suggestions, Dr J. Roberts for providing purified recA protein, and Dr Chung for his assistance in performing certain of these experiments.

Requirement of nifV gene for production of wild-type nitrogenase enzyme in Klebsiella pneumoniae

P. A. McLean & R. A. Dixon

ARC Unit of Nitrogen Fixation, University of Sussex, Brighton BN1 9RQ, UK

Klebsiella pneumoniae nitrogenase is a complex enzyme consisting of two component proteins, the tetrameric MoFe protein (Kp1) and the dimeric Fe protein (Kp2)1. Together these catalyse the ATP-dependent reduction of N2 and of several triple-bonded substrates such as C2H2, CN, N3 and CH₃NC (refs 2, 3). In the absence of substrate, protons are reduced to H2 and all substrates compete with protons for reduction. Carbon monoxide inhibits all reductions except H2 evolution4. Seventeen genes are required for the synthesis of nitrogenase and expression of its activity in K. pneumoniae 5-8, some of which are believed to be involved in processing of the nitrogenase proteins during synthesis 9,10. Here we describe studies of the nitrogenase of bacteria mutated at one of these genes-nifV. These mutants produce nitrogenase which does not reduce N2 in vivo, although it does in vitro in conditions of high electron flux. We show that the defect is in the Kp1 component, and suggest that the nifV gene product modifies the Kp1 component so that N2 reduction will occur at the lower electron fluxes present in vivo, and that this might have been involved in the possible evolutionary development of the nitrogenase from a cvanide-detoxifying enzyme.

nifV mutants were originally isolated by their inability to grow anaerobically (anaerobic conditions are required because oxygen represses nitrogenase production) on nitrogen-free medium, but all nifV mutants were shown to give a leaky phenotype when assayed for C_2H_2 reduction^{5,6}, a test normally accepted as indicative of N_2 -reducing ability. Indeed, some nifV::Tn7 mutants gave 50–100% of wild-type C_2H_2 -reducing levels even though such mutations should completely inactivate the nifV gene product in most cases⁶.

To test the true nitrogen-fixing ability of nifV strains, derepressed cultures were incubated under an atmosphere of 15N2 and after 11 h cell pellets were collected for 15N analysis (Table 1). The two nifV::Tn7 mutants gave no significant incorporation of ¹⁵N into cell material whereas these mutants significantly reduced C₂H₂, indicating that derepression had occurred (Table 1). Failure to incorporate ¹⁵N₂ was not due to defective assimilation of fixed nitrogen^{11,12}, because both mutants utilized histidine, arginine, tryptophan and nitrate as sole nitrogen sources aerobically and nitrate and arginine anaerobically. If N₂ cannot act as a substrate for the enzyme the presence of N2 might not affect C₂H₂ reduction. Figure 1 shows the effect of N₂ on in vivo C₂H₂ reduction by whole cells of a nifV mutant (UNF1613) and a wild-type control (UNF3001). C₂H₂ reduction by wildtype cells was noticeably inhibited by 0.1 atm and 1 atm N₂ whereas C₂H₂ reduction by the mutant was not. UNF3001 and UNF1613 had a K_m for C_2H_2 of 4.2 and 4.6 atm, respectively. We conclude that nifV insertion mutants are unable to reduce

This inability of nifV mutants to reduce N_2 could be due to an excess of Kp1 over Kp2, resulting in a situation favouring C_2H_2 reduction $^{13.14}$. Crude extracts of nifV and wild-type strains were thus tested for the relative levels of the two nitrogenase proteins by rocket immunoelectrophoresis using purified proteins as standards. These showed that UNF3001, UNF1610 and UNF1613 crude extracts had an $in\ vivo\ Kp2$: Kp1 molar ratio of 6.6, 5.2 and 4.7, respectively. These results are not significantly different and confirm the conclusion 15 that there is an effective excess of Kp2 $in\ vivo$. However, this assumes that all cross-reacting material is catalytically active. Unfortunately, direct activity measurements on the individual nitrogenase proteins in crude extracts is complicated by their interdependence for

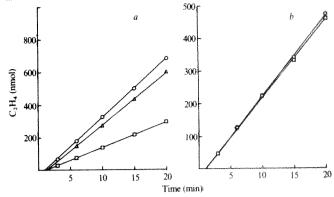

Fig. 1 Time course for in vivo C_2H_2 reduction by wild-type (UNF3001) (a) and nifV mutant (UNF1613) (b) cells at 0.0074 atm C_2H_2 . Cultures were grown in NFDM+arginine (1 g l⁻¹) for 20 h at 30 °C with constant N_2 bubbling. They were collected by centrifugation under argon and resuspended in cold argon-bubbled NFDM+chloramphenicol (0.1 g l⁻¹) and kept on ice under argon. Samples (5 ml) were taken by syringe into 30-ml flasks flushed with either argon or N_2 and incubated for 10 min at 30 °C before addition of 0.25 ml C_2H_2 to start the reaction. Headspace samples (0.5 ml) were taken at intervals and analysed by gas chromatography. Assays under 0.1 atm N_2 were set up by adding 3.0 ml N_2 to the 29-ml headspace. \bigcirc , 1 atm A_1 ; \triangle , 0.1 atm N_2 in A_1 (wild type only); \square , 1 atm N_2 .

substrate reduction. An indirect estimate of the extent to which Kp1 is saturated with Kp2 in crude extracts can be measured by observing the increase in C_2H_2 -reducing activity on addition of excess purified Kp2. Figure 2a shows the effect of adding a >10-fold molar excess of purified Kp2 protein to crude extracts of a wild-type and nifV strain. Kp2 addition stimulated C_2H_2 -reducing activity to approximately the same extent in both crude extracts. Thus, an unfavourable Kp2 Kp1 ratio is unlikely to account for the inability of nifV cells to fix N_2 in vivo.

Figure 2b shows hydrogen evolution by crude extracts under various atmospheres and the effect of added Kp2. Control assays omitting either ATP or dithionite showed that <10% of H₂ evolved in assays with added Kp2 was attributable to other hydrogenase activity. Nitrogen failed to compete with protons in assays with mutant extracts even with the addition of a sevenfold molar excess of Kp2 (maximum 6% inhibition of H2 evolution) whereas significant competition (63% inhibition) was seen in assays of the wild-type extract even without added Kp2. Thus, the nifV crude extract is apparently defective in reducing N2 as a substrate, although it reduced CN and CH3NC (data not shown). CO alone or CO plus C2H2 did not significantly affect H2 evolution in the wild-type extract (Fig. 2b). (The combination of CO plus C₂H₂ inhibits reversible hydrogenase without affecting H₂ evolution by nitrogenase¹⁶.) However, hydrogen evolution by nifV crude extracts was inhibited 50% in the presence of 3%

Table 1 Incorporation of ¹⁵N₂ by cultures of K. pneumoniae nifV mutants

Strain	Genotype	Specific activity of C ₂ H ₂ reduction (% of wild-type)	Atom % 15N enrichment
UNF2036	$nif\Delta$	<1	< 0.4
UNF3001	nif ⁺ (wild-type)	100	21
UNF1610	nifV2249::Tn7	61	0.7
UNF1613	nifV2253::Tn7	81	0.5

Strains were grown under a stream of N_2 for 8 h at 30 °C in nitrogenfree Davis and Mingcoli medium $(NFDM)^6$ arginine $(1\ g\ l^{-1})$ to permit derepression. Cells were collected by centrifugation, resuspended in fresh Argon-bubbled NFDM+ arginine $(1\ g\ l^{-1})$ and shaken for 11 h at 30 °C under 63% N_2 (70% enriched for $^{15}N_2$) in argon. Cell pellets were collected by centrifugation and digested for ^{15}N analysis by mass spectroscopy. C_2H_2 reduction was measured before incubation under $^{15}N_2$ as in Fig. 1 except that 2.0 ml of culture was used.

Table 2 Effect of varying the molar ratio of purified Kp2 and nifV Kp1 on substrate reduction

	Kp2:Kp1			of substrate reducemin per mg Kp1)	tion	% Inhibition	Electron flow under N ₂
Source of Kp1	molar ratio	H ₂ under argon	H ₂ under N ₂	NH ⁺ production	C ₂ H ₂ reduction	of H ₂ evolution by N ₂	Electron flow under Ar
UNF1613 nifV::Tn7	1:1	182	155	17.8	152	-3 - 2	
UNF1613 nifV::Tn7	2::1	399	340	73.5	152	15	100
UNF1613 nifV::Tn7	4::1	763	503	157	320	15	113
UNF1613 nifV::Tn7	7::1	1.022	717		620	34	97
UNF1613 nifV::Tn7	10::1	1,022		259	843	30	108
UNF1613 nifV::Tn7	25::1	,	842	318	1,044	32	106
MSal wild type		1,532	938	370	1,262	39	97
	1::1	249	94.4	113	247	62	102
M5al wild type	10::1	1,527	471	725	1,127	69	102

Assays were done with 0.22 µM MoFe protein either under 1 atm Ar, 0.13 atm C₂H₂ in Ar or 1 atm N₂ at 30 °C, and were linear with time. H₂, C₂H₄ and NH⁺₄ were determined as described previously21. Specific activities in nmol C2H4 reduced per min per mg protein in optimal conditions were nifV Kp1, 1,262; wild-type Kp1, 1,240; wild-type Kp2, 1,150. Component ratios were calculated assuming a maximum specific activity for C2H2 reduction of 1,800 nmol per min per mg for both Kp1 and Kp2.

CO or CO plus C₂H₂. Thus ATP- and reductant-dependent H₂ evolution by nifV nitrogenase is inhibited by carbon monoxide, in contrast to wild-type enzyme.

The failure of added Kp2 to stimulate N₂ reduction might be due to inhibition by defective Kp2 in the mutant crude extract, a situation analogous to certain heterologous combinations of nitrogenase components from different organisms 17-20. Following purification of Kp1 and Kp2 from UNF1613 by conventional procedures 19,21,22, Kp2 from the nifV mutant showed wild-type properties with respect to N₂ reduction and CO insensitivity of H₂ evolution when complemented by wild-type Kp1 protein. The nifV Kp1 showed CO inhibition of H₂ evolution when complemented with wild-type Kp2 (Fig. 2c). These mutants therefore have a defective MoFe protein.

Table 2 shows the effect of the Kp2: nifV Kp1 molar ratio on substrate reduction. The rate of substrate reduction increased with increasing Kp2: Kp1 ratio. The rate of NH₄ production by the mutant Kp1 increased with ratio but was less than half the wild-type rate at a 10:1 ratio. Even at a 25:1 ratio only 39% of the electron flow was utilized for NH₄ production, compared with 62% for a 1:1 ratio with wild-type Kp1. However, the rate of electron flow through both mutant and wild-type enzyme was the same under either argon or nitrogen (Table 2 and ref. 23). Clearly, N₂ reduction by nifV Kp1 only competes effectively with hydrogen evolution at non-physiological molar ratios of the two proteins, whereas C₂H₂ reduction seems to be normal. The

a, C₂H₂ reduction by UNF3001 (wild type, WT) and UNF1613 (nifV) crude extracts with (unshaded) and without (shaded) added Kp2; b, H2 evolution by crude extracts under argon; N₂; Ar+3% CO; Ar+CO+14% C₂H₂. 20-min assays were done as in ref. 21. Cells for crude extract preparation were grown for 17-18 h in 20 l Ar-bubbled NFDM + NH₄Cl (0.24 g l^{-1}) Sodium aspartate was added (50 mg l^{-1}) and the pH adjusted to 7.2. After 5 h derepression, cells were collected by centrifugation anaerobically, resuspended in 30-45 ml 50 mM HEPES pH 8.7, 0.65 mM dithiothreitol and 2 mM $Na_2S_2O_4$, crushed at 12,000 Pa in a French pressure cell and cleared by centrifugation at 38,000g for 45 min. The supernatant was frozen in liquid N₂ and stored at -196 °C. Assays²¹ contained 1.03 mg (UNF3001) and 1.54 mg contained 1.03 mg (UNF3001) and 1.54 mg (UNF1613) protein and were linear with added protein. Kp2 (specific activity 900 nmol C₂H₂ per min per mg) was added at 0.151 mg per assay where appropriate. c, H_2 evolution by purified nif V Kp1 and a 10-fold molar excess of wild-type Kp2 under argon with and without 5.8 matm carbon monoxide.

discrepancy between the lack of N2 reduction in vivo and in crude extracts compared with the measurable rates with purified enzyme may reflect the presence of other proteins in the former which affect the rate of nitrogen reduction.

Recent in vitro studies with purified nitrogenase components have shown that the distribution of electrons between competing substrates depends on the rate of electron flux through the MoFe protein and that this is influenced by the ATP concentration and the Fe: MoFe protein ratio 13,14,24. The electron flux increases with increasing Fe protein: MoFe protein ratio 24,25 and whereas low electron fluxes favour proton reduction, progressively higher fluxes favour C₂H₂ and N₂ reduction in that 25. As nifV Kp1 does not respond normally to Kp2 addition, what is the function of the nifV protein? We conclude that it processes the MoFe protein, and that this modification renders H₂ evolution insensitive to CO inhibition. Furthermore, the nifV product seems to modify the catalytic ability of Kp1 so that N₂ reduction will occur at a lowered electron flux. It has been suggested that nitrogenase was originally a cyanide detoxifying enzyme²⁶. We suggest that the nifV modification might be a later evolutionary development which converted the original enzyme into an efficient nitrogenase. Finally, like other workers^{14,17}, we stress the need for caution when using the C₂H₂-reduction test as a measure of nitrogen fixation. The study of the nifV MoFe protein may provide useful insights into the structure of the MoFe protein of nitrogenase and its mechanism of substrate reduction.

We thank Professor J. R. Postgate and Dr R. Richards for helpful suggestions, Dr B. E. Smith for useful discussions and for donating purified wild-type nitrogenase components, E. Kavanagh for performing the ¹⁵N digestion and analysis, and Mr K. Baker for growth of cells for protein purification. P.A.McL. is the recipient of a research assistantship from the Agricultural Research Council.

BOOK REVIEWS

Synaptic patterns of the mind

H.B. Barlow

THIS book is based on a Work Session of the Neurosciences Research Program that was held in May 1978, but although it is thus based on papers given at a conference three years ago it is very much alive and worth reading by those interested in theoretical approaches to the nervous system. The editors have evidently made a determined effort to present the material as a coherent whole in a readable form, and to a large extent they have succeeded. They divide the material up into three levels: the nature of the computations that are needed for the sensory and motor tasks we perform, the algorithms by which the computations are achieved, and the biological mechanisms which perform them. These are dealt with in reverse order. neural mechanisms first and the nature of the computation last; the recognition of the three levels provides a convincing framework for describing selected aspects of the enormously complicated processes that underlie our perceptions and control our movements. The book not only has a unified viewpoint but also an original feature here visible, I think, for the first time. This is the attempt to provide a theoretical background, together with a shorthand graphical representation, for the non-linear interactions on which the crucial logical operations of the nervous system depend. However let us first consider the review chapters, which are still useful even though not fully up to date.

The first section has four chapters on how the nervous system performs its computational algorithms. The first two are useful general reviews by T. Lamb and D. Baylor on the biophysics of transduction in photoreceptors and the integration and transmission of this information through the retina. These look upon signal generation and transmission as linear processes, but the next two chapters by T. Poggio and V. Torre are the ones in which a biophysical mechanism for the non-linear interactions that must underlie pattern selective mechanisms are proposed, and I shall return to them for they form the book's kernel of originality.

The next section has seven chapters at the level of "algorithms and interactions" in neural systems. It contains up-dating reviews on various aspects of the visual system by Victor, Poggio, Reichardt, Wilson, Julesz, Hubel and Cowan. As the editors seem to admit, it is not quite right to apply the term "algorithm" to what is here described. An algorithm surely has a clearly defined purpose, but we are almost completely ignorant of the purposes of

Theoretical Approaches in Neurobiology. Edited by W.E. Reichardt and T. Poggio. Pp.252. ISBN 0-262-18100-2. (MIT Press: 1981.) \$27, £14.

non-linear interactions in the cat's retina, cooperative processes in texture perception or the columnar organization of the visual cortex. All the same one needs a level of description intermediate between biophysics and artifical intelligence or cognitive modelling. Anyone who has tried to understand someone else's computer program, or even one of his own, will recognize the dazed feeling that accompanies the question "What in the world does this page of nonsense accomplish?", and that is the feeling one has when reading much of this middle section of the book. Of course something is accomplished, but the interpretive keys are in many cases unknown, or at any rate not divulged.

The level of the final section is that of describing the nature of computations. Two of them deal with visual control of flight in flies (Reichardt and Poggio), and of limb pointing in monkeys. The other two are concerned with human perception. Ullman deals at a theoretical level with the remarkable human capacity to interpret the relative motions of a few isolated spots of light in terms of the coherent motion of a single rigid object. Marr's chapter gives a brief summary of his approach to vision, and it would form a very useful introduction to his work for someone who has not read his lengthier papers. It is clear that this book as a whole owes a great deal to Marr's recognition of the different levels of description that are required in order to understand visual perception.

Tomaso Poggio, as well as editing the book, is author or co-author of at least 25 per cent of the material in it, and in these sections an important new approach is set out. As Boole realized when he wrote the "Laws of Thought" more than 100 years ago, higher mental processes require logical operations that are essentially nonlinear and more like multiplications than addition or subtraction. He was of course thinking of mental processes at a verbal level, but the lesson must also apply for the pre-verbal processes that underlie pattern selectivity and motor control, and it is the mechanism and organization of these processes at the level of the synaptic interactions between cells that Poggio and Torre attack in the biophysical section of this book. The intracellular potential of a particular cell has customarily been regarded as summating the positive and

negative influences of all the neurones that make excitatory and inhibitory synaptic connections with it. Poggio and Torre point out that synapses situated close to each other on one of a cell's dendrites will mutually influence each other, and the effects produced at a distant point will not simply represent the sum of the two. For instance, if one synapse is inhibitory and acts by increasing conductance to an ion whose concentration ratio is close to that corresponding to the cell's resting potential, then its activation will contribute very little potential change at a distant point in the cell. Nevertheless it may have a very powerful effect in stabilizing the potential at that point in the cell when a neighbouring excitatory synapse becomes active. This shunting effect can be very powerful, but will only be local. They propose that this may be the mechanism whereby directional selectivity is achieved in retinal ganglion cells, and it certainly fits two of the main requirements deduced from physiological analysis, namely that the interactions responsible are between local sub-units of the receptive field of a retinal ganglion cell, and that they are inhibitory in nature. The logical operation is thus equivalent to "and not", or one input vetoing another, rather than to the conjunctive "and".

The development of this idea is given in some detail, made more digestible by placing much of the mathematics in an appendix, as is also done in the rest of the book. Unfortunately, though the ideas are important for a large number of people, it is not very easy to follow. The authors have sought clarity in exactitude, whereas a certain amount of over-simplification might have been more effective. They also invent an interesting graphical notation which has symbolic representations for conductance changes as synaptic inputs, for the currents thereby produced and the potential changes resulting from the filterlike action of decremental electrotonic conduction, and most important, for the multiplicative effect of a conductance change on a voltage. If this notation is developed, and is adopted, one may be able to "read" a neural circuit in the same way that one can transistor circuits. It may even be possible to relate such a graphical form of neural circuit to the synaptic anatomy visible by electron microscopy, for many important quantities determining nonlinear interaction are dependent upon anatomical variables such as proximity and dendritic diameter.

Neurophysiology is mainly a simple

science, and I am not sure that Poggio has expressed his ideas in a simple enough form for us to understand. But this part of the book is certainly a novel attack on a most important problem, and one leaves the book as a whole in a rather more optimistic mood than is usually the case after a dose of brain theory. Instead of feeling that the subject matter is incoherent and totally unapproachable, one feels that, within the framework set out, the brain may, ultimately, become comprehensible.

Not quite Allard

C.N. Law

The Theory of Plant Breeding. By O. Mayo. Pp.293. ISBN 0-19-854536-3. (Clarendon/Oxford University Press: 1981.) £30, \$89.

PLANT breeding has long required an upto-date and authoritative textbook. It is now over 20 years since what many regarded as a good book on the subject, Principles of Plant Breeding by R.W. Allard (Wiley, 1960), first appeared. Since that time numerous attempts have been made to write a worthy replacement but with limited success. This book on the theory of plant breeding, by O. Mayo, is likely to receive a similar assessment. This is a pity, since the book has merit and touches on much that needs to be said about plant breeding and related sciences.

The book has 17 chapters, of which seven of the longest describe methods of genetic analysis, the properties of genetic systems in inbreeding and outbreeding crops, the response of such systems to environmental variables and different selection pressures. These are then followed by several short chapters on induced mutation, disease resistance, somatic cell genetics and, as if as an afterthought, further cytogenetical manipulations. The final chapters discuss the conservation of germplasm and aspects of plant breeding strategy.

A number of errors occur, mainly of omission. Thus, the author is rather cursory in his treatment of the covariance-variance analysis of diallel crosses, and is apparently not aware that the creators of this analysis have been at pains to point out its weaknesses in detecting certain types of gene action. Likewise, the treatment of the genetical causes of heterosis leaves much to be desired, particularly since the author appears to labour under the misconception that heterosis is a phenomenon still awaiting a genetical explanation.

Far too frequently important methods and issues are mentioned en passant, when

Entomology — and how the West was won

Philip S. Corbet

From Arsenic to DDT: A History of Entomology in Western Canada. By Paul W. Riegert. Pp.357. ISBN 0-8020-5499-4. (University of Toronto: 1981.) \$30. To be published in the UK on September 24, £18.

THE history of Canadian entomology has received close and expert scrutiny before. Compared with two previous accounts by R. Glen (Can. Ent. 88, 290-371; 1956) and G.J. Spencer (Can. Ent. 96, 33-59; 1963) - Professor Riegert's attractively presented book is narrower in scope but much more detailed. It traces the development of entomology (mainly applied entomology) in the four western provinces of Canada, from the arrival of the first European colonists until just after the Second World War, when synthetic organic chemical insecticides were starting to transform the practice of pest control. (The history of forest entomology is omitted because Riegert discovered that such a document had recently been prepared.) As it stands, this book provides a wealth of detail on subjects as varied as the daunting mosquito attacks recorded by traders in the early seventeenth century, instructions for making and applying "Criddle Mixture" (a horse-manure-based poisoned bait for grasshoppers) and the progressive evolution and enforcement of interprovince quarantine regulations.

The five main parts of the book are devoted to encounters between European colonists and insects; the first professional entomologists; the insects of British Columbia — mainly mosquitoes and orchard pests; the insects of the prairies — including the wheat-stem sawfly, grass-hoppers, cutworms and wireworms; and specialized topics such as medical and veterinary pests, stored-products insects, and the teaching of entomology in universities.

A brief, admirably succinct, epilogue reviews the main personalities and events which attended the growth of applied entomology in western Canada from the 1880s to the 1950s — "from arsenic to DDT" — and ends by listing some of the lessons to be learnt from this richly documented set of case studies.

The author's style tends to be somewhat florid for my taste, and his inclusion of diverse anecdotal and factual material at times impairs the fluency of the text, although this seems a modest price to pay for the exhaustive background information he provides. A map would have been a useful adjunct to the excellent contemporary photographs.

This book will certainly appeal to those wishing to learn, or to be reminded of, the circumstances and individuals that have helped Canadian entomology to become so vigorous and effective; and, for the sake of the discipline's continuing health, one may wish that such readers will include those who decide the resources to be allocated to entomology by future Canadian governments! As a contribution to the existing literature on the history of entomology, Riegert's book has undoubted value in several other respects. Using a canvas of manageable size, he delineates the changing pattern of agricultural and veterinary entomology in a developed, though recently settled, country which is prone to severe pest problems. The extremely detailed description of these problems - including contemporary recipes for their mitigation and the frank but sensitive description of the men and institutions concerned with pest management, may attract the interest of social historians as well as applied entomologists. One may hope that those destined to practise and administer applied entomology in Canada and elsewhere properly appreciate the realities of largescale pest suppression when synthetic organic chemical pesticides are not available. People who read this book will surely gain such an appreciation; and in doing so they will come to share the author's high regard for the immensely able and resourceful pioneer entomologists who successfully tackled some of the most intense insect attacks ever to be endured by human beings.

Philip S. Corbet is Professor of Zoology at the University of Dundee, and was formerly an entomologist in Canada.

more detailed and penetrating accounts are demanded. This is a disappointing feature which probably arises from the stated objectives of the book, which are to give an account of plant breeding theory but not to provide extensive descriptions of proofs or methods. However, one questions whether this is a wise decision when such an important aspect as breeding for disease resistance receives only three pages of text. The impression emerges that the author has much to contribute in writing about the

theory of plant breeding; but either he has been overly constrained by limitations on the size of the book or he has been perhaps too unambitious in his objectives. He should be encouraged to build upon the firmer foundations of this book as well as to include views about the practice of plant breeding in any future edition.

C.N. Law is Head of the Cytogenetics Department at the Plant Breeding Institute, Cambridge.

Illiterate lamp men and other problems in geodesy

William M. Kaula

Geodesy, 4th Edn. By G. Bomford. Pp.855. ISBN 0-19-851946-X. (Oxford University Press: 1980.) £49. \$139.

In 1952 I was reassigned from a combat engineer battalion in the Fulda Gap to the Ohio State University in order to study geodesy. Upon arriving in Columbus that June, I met Professor W. A. Heiskanen, who said: "I'm going to Finland tomorrow for the summer. Here, study this book". "This book" was the first edition of Bomford's Geodesy, just published. So that summer I spent many hours between classes under the trees (now gone) on the east bank of the Olentangy, gleaning geodesy from Geodesy.

Geodesy is a compendium, rather than a textbook or a treatise. It is the principal geodetic reference book in English. The main parts of this new edition are: horizontal control (196 pp.), vertical control (57 pp.), physical geodesy (118 pp.), artificial satellites (139 pp.), and appendixes and bibliography (186 pp.).

Virtues of the book and its author include comprehensiveness within geodesy, a strong geometrical intuition, keen insights about instrumentation and observations, a sensitivity to measuring errors - and good writing. Bomford has much better command of language than most scientists and engineers. His discussions of such topics as the effects of atmospheric refraction on theodolite or spirit-level measurements are a pleasure to read, being syntheses of practical experience, an analytical attitude and fluency of expression. His Indian past is manifest in passages such as "When supplies and transport are easy and with lamp men who can find their own way about, the programme presents no special problems, but in uninhabited country, or with illiterate lamp men, it calls for very careful thought . . . ". Bomford's careful selection of tangential topics, practical (e.g. star catalogues) or scientific (e.g. geophysical implications of gravity anomalies) is also evident.

However, he is less at ease with the abstract and the mathematical. His treatments of potential fields and orbital dynamics are somewhat perfunctory, and these topics are made unnecessarily obscure by quoting complicated formulae, rather than discussing underlying principles. A saving grace is the frequent referencing; anyone trying to use Geodesy as a text (as I did) must resort to looking up the references to understand whence came

The first of a new series, Current Reviews in Biomedicine, has been published by Elsevier/North-Holland. The paperback Towards Understanding Receptors, edited by J.W. Lamble, is a well-organized collection of 33 reviews largely taken from Trends in Pharmacological Sciences, and costs £7, \$25.

many of the prickly-looking equations. Oddly incongruous with the quoted formulae in the main text are most of the appendixes, which include rather elementary explanations of matrix algebra, theory of errors, vectors and so on. Some of this matter is outmoded: for example, eight pages on the solution of matrix equations make no mention of square-root techniques, while four pages on harmonic analysis reference only books written before 1930, and do not mention fast Fourier transform methods. Such archaisms may unduly deter those who have had modern engineering educations from using the book.

The revisions between the 1971 and 1980 editions are major. The type appears to have been completely reset and the size of the book has risen by 17 per cent. This increase is almost entirely explicable by the greater space accorded to artificial satellite methods, which has not only more than tripled but has also been rearranged with respect to the other material. However, going through the two editions in parallel reveals many other detailed changes, such as increases in the space devoted to crustal movements, time standards, MSL-geoid difference and gyro-theodolites which are balanced by decreases in that allocated to map projections, mechanical chronographs, astrolabes etc. In the earlier parts, particularly, this compressive zeal was paragraph by paragraph. A loss of flavour sometimes results. Thus, what was in the 1952 edition:

Such an apparatus was used in India in 1880 [150], p.35, and another was used with the prismatic astrolabe in 1927-9 [151], but neither was entirely satisfactory. Possibly the principle was sound, but the mechanism imperfect. Recently R. Woolley (of the Commonwealth Observatory, Canberra) has made an apparatus on similar lines, which is reported to be satisfactory in the observatory, although possibly not easily portable. Full reports have not yet been published.

has now shrunk to: "Such an apparatus has been constructed from time to time, but no great use of the method has been reported". Unfortunately, this drive to prune and mend apparently flagged by the time the appendixes were reached.

Bomford's experience and perception in geodetic survey is particularly applicable to current problems of using past geodetic measurements to infer crustal movements. The relevant cautionary remarks appear in both the sections on control and those on crustal movements: for example "The differences cannot lightly be ascribed to crustal movements", and "Levelling has sometimes been less good than it looks". Several likely systematic errors are discussed, but the bite of specific examples is lacking, perhaps because the Survey of India was always stricter in its practices

than was the US Coast and Geodetic Survey.

I must report that I found no errors, other than a few misprints. The defects are much more ones of selection and exclusion. In addition to those mentioned above, an oddity is the omission of the determination of longitudinal variations in the gravity field from satellite orbit perturbations, which is both conceptually simpler and more fruitful of geodetic results than the resonant effects which are included.

Nonetheless, if you have a geodetic problem, look it up in Bomford. If he doesn't give you the answer, he'll tell you where else to look.

William M. Kaula is a Professor of Geophysics at the University of California, Los Angeles.

Material attraction

P. J. Grundy

Ferromagnetic Materials: A Handbook on the Properties of Magnetically Ordered Substances. Vols 1 and 2. Edited by E.P. Wohlfarth. Vol.1 pp.634, ISBN 0-444-85311-1. Vol.2 pp.600, ISBN 0-444-85312-X. (North-Holland: 1980.) Each volume Dfl.210, \$102.50.

Many textbooks and technical handbooks lay claim to the title of the definitive text. However, in order to prove its superiority over all comers, a book, like all championship contenders, must have all the necessary qualities. If all the promised material — a further two volumes are planned — is provided and published within a reasonable time, this work should, indeed, prove to be a champion.

The handbook is designed to cover as wide a range of material properties as possible. Its restrictive title of Ferromagnetic Materials is quickly extended by the subtitle to take account of the other varieties of magnetic ordering, and the subjects covered by the first two volumes are varied indeed. The contributing authors have been well chosen, are "experts" in their specialist fields and most are household names in magnetism.

Understandably, there is no obvious overall plan to the layout of the chapters, except that the first is by the editor and reflects his deep interest and involvement with work on the trio of ferromagnetic transition metals. The second chapter of the first volume, by Mydosh and Nieuwenhuys on dilute transition metal alloys, deals authoritatively with the complex and fascinating range of effects arising from the concentration changes and differing magnetic interactions of the

magnetic impurity in these spin glass systems. This first volume also contains contributions on rare earth metals and alloys and compounds by Legvold, Buschow and Clark. Each of these authorities has worked on these fundamentally important, numerous (Buschow lists details and references to at least 1,000 binary and ternary compounds) and potentially useful materials since the 1960s. The journey through the periodic table is completed by Trzebiatowski's contribution on actinide elements and compounds. Even for many people active in magnetism, these materials are somewhat enigmatic. However, their properties are clearly dealt with and no text could claim to be comprehensive without their inclusion. As might be expected, the chapter on amorphous magnetic materials prepared by rapid quenching from the melt is an especially authoritative and lucid account; Luborsky and co-workers have been pace-makers in the study of the magnetic properties and preparation methods of these alloys, especially those suitable for the application and production of commercially useful material.

The second volume is dominated by contributions from the research and development laboratories of large industrial corporations. This is an important and welcome feature for several reasons. One is that it brings home to the reader, especially in the chapters on bubble domain materials by Eschenfelder, where charts in which interrelated material properties and parameters can be crosschecked are given, the special approach to research which is concerned with designing and using materials in a real application. Another is that articles, such as those by Chin and Wernick on soft magnetic materials and Bate on magnetic recording materials, are extremely comprehensive and are accompanied by exhaustive reference lists — presumably the product of excellent information retrieval systems. On the other hand, the smaller corpus of knowledge on other materials, and perhaps a more selective approach, is evident in some of the other contributions. This also has its advantages in that it can be said that part of the author's responsibility is to guide the reader and select the important contributions to his subject.

The four articles by Gilleo, Slick, Nicolas and Eschenfelder on the magnetic ferrites and garnets cover the ground admirably. The final chapter by Charles and Popplewell is, not surprisingly, the only contribution on materials which are effectively liquids. "Ferrofluids" present a challenge in thought as to what uses can be made of magnetizable colloidal suspensions. Several applications have already been addressed but one severe problem seems to be the rapid departure from liquid behaviour accompanying only modest increases in concentrations and magnetization.

There is no doubt that these volumes

should be available in all research and development laboratories concerned with magnetic materials and material properties in general. Their value as sourcebooks to both graduate students and seasoned researchers is obvious, and their appearance will help to promote the important messages that magnetic materials display a bewildering variety of properties and that the applications of magnetism

permeate the whole of modern society by providing electric power, communications and information storage. I am sure the international magnetism community awaits with anticipation the volumes yet to appear.

P. J. Grundy is Senior Lecturer in the Department of Pure and Applied Physics at the University of Salford.

Mathematical stimulus for biologists

J.D. Murray

The Geometry of Biological Time. By Arthur T. Winfree. Pp.530. ISBN 0-387-09373-7/3-540-09373. (Springer-Verlag: 1980.) DM 59.50, \$32.80.

GENUINE interdisciplinary research can often produce spectacular and exciting results. Winfree, a biologist, knows a lot of mathematics and this book reflects his appreciation of interesting problems in both fields. Amongst other things he gives some excellent case histories of what interdisciplinary endeavour can achieve. There is no doubt that the development of models and model mechanisms as an aid in elucidating biological phenomena with a view to determining basic principles is a flourishing, useful and fascinating area of research. (The interdisciplinary mathematics-biology fields are now recovering from the ravages caused by catastrophe theory.) In many countries the generous support from research funding organizations reflects this growth area.

This book is a major contribution to theoretical biology and will become, I am sure, an essential reference book for those, theoreticians as well as experimentalists, interested in modelling and understanding periodic behaviour in biology. From a pedagogical point of view it does not require much detailed knowledge of mathematics as such, except for selected chapters, but it does require a mathematical appreciation and understanding which most bioscientists do not have. However, those with firmity of purpose. who persevere with most of the more instructive first nine chapters, will reap rich rewards. Those with less time or weaker will can usefully go to those parts of the second half of the book which deal with more specific phenomena. Many of the ideas and concepts described are illustrated with relevant, and often ingenious experiments.

Winfree first discusses periodic behaviour in general, phases, phase singularities and phase resetting. The latter is shown to be an important concept of relevance to experimental observation. The effect of interactions between oscillators is then examined. In particular, where they are spatially distributed they can result in a variety of unexpected wave phenomena. One of Winfree's aims is to try to give a picture of observed events and natural phenomena which are not dependent on specific models. Generally he uses a geometric conceptual approach.

The second half of the book deals mainly with specific phenomena and experiments which exemplify some of the ideas developed earlier, but can be read, more or less, independently from the first half. Here Winfree discusses several major topics of current biological research and among other things gives his personal views on them. For example, such topics as the Belousov-Zhabotinskii reaction (emphasizing the wave phenomenon aspect), slime mould aggregation, circadian rhythms in insect eclosion, the female cycle and the cell mitotic cycle are surveyed and discussed. Researchers in each of these areas, and others covered, will no doubt feel that the views expressed do not give the whole picture of current thinking (and how could they in a single book?) or present a biased picture, and so on. This indeed so, but whatever their views, it will be difficult to ignore many of Winfree's ideas with impunity.

This book exhibits a remarkably wide spectrum of biomedical problems of current research interest. With Winfree's talent in presenting succinctly the essential interesting features of a phenomenon, it is accessible to most mathematicians, physical scientists, and with somewhat more effort, bioscientists who believe in the use of models in biology (and few can now admit to a contrary view). Parts of it can be usefully given to both undergraduates and graduate students. I strongly recommend it for those seriously or casually interested in modelling and understanding biological oscillators and their role in nature: the book is full of unanswered questions and research ideas. As an introduction for the uninitiated, and a stimulant for the cognoscenti, it is excellent, lucidly and anecdotally written, and has a well-vetted bibliography.

J.D. Murray is Reader in Mathematics at the University of Oxford with research interests in theories of biological pattern formation.

ANNOUNCEMENTS

Awards

Prof. Choh Hao Li (Director of the UC-San Francisco Hormone Research Laboratory) has received the Fred Conrad Koch Award research on the hormones of the pituitary gland.

The Geological Society of London has made the following awards: The Wollaston Medal to Prof. R.M. Garrels; The Murchison Medal to Prof. G.M. Brown; The Lyell Medal to Dr W.S. McKerrow; The Prestwich Medal to Dr H.G. Reading; The Bigsby Medal to Dr A.G. Smith; The Wollaston Fund to Prof. John Murray; The Murchison Fund to Dr A.H.G. Mitchell; Moieties of the Lyell Fund to Dr M.G. Bassett and Dr B.J. Bluck; President's Awards to Dr A. Saunders and Dr A. Scott; The R.H. Worth Prize to Mr E.H. Shackleton.

Through the Irish Foundation for Human Development, the Curt P. Richter Prize in Psychoneuroendocrinology has been established for meritorious research in the area of Psychoneuroendocrinology. The sum of \$1,000 will be awarded annually for the best essay or manuscript submitted by a scientist or physician under 40 years of age by I January 1982. Manuscripts (in quadruplicate) to: Dr Fleur L. Strand, Secretary, International Society of Psychoneuroendocrinology, Biology Department, New York University, 952 Brown, 100 Washington Square, New York, New York 10003, USA.

Churchill Travelling Fellowships are open to all UK citizens of any age or occupation; no educational or professional qualifications are needed. The awards enable candidates to gain a better understanding of the lives and work of people in countries overseas, and to bring back useful knowledge for the benefit of the community. Grants are offered in different categories each year (for example "Medical Research into the Relief of Pain" will interest scientists, doctors and research workers associated with the development of new methods to alleviate suffering; and "Animal Welfare Legislation" will interest those concerned with the preparation and application of animal welfare legislation relating to husbandry, laboratory, game laws and wildlife conservation. The grant will cover return air fare, plus travel and living expenses abroad for a period of up to three months. To apply send your name and address only on a postcard between August and Mid-October to the Winston Churchill Memorial Trust, 15 Queen's Gate Terrace, London SW7, UK.

Conditions of Service: Both permanent pensionable terms and short-term contracts are offered for academic posts.

Further Particulars on the above posts, on conditions of service and on method of application should be obtained prior to submitting an application from Director, Appeintments and Personnel, University of Zimbabwe, PO Box MP167, Mount Pleasant, Salisbury, Zimbabwe, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF.

Applications should be submitted by 31 August 1981. (9293)A

Senior Cardiovascular **Pharmacologist** (Haemodynamics)

Haessle is a rapidly expanding research and marketing organisation within Astra Pharmaceuticals, Sweden.

Our activities are internationally oriented and concentrate on the development and marketing of drugs for cardiovascular and gastrointestinal disease. The research organisation currently has a gastrointestinal disease. The research organisation currently disease. The research organisation currently staff of about 300. We now urgently need to fill a new(?) position of Senior Pharmacologist (Section Head) within the department of Cardiovascular Pharmacology (Head: B.AABLAD). The person in this position will be responsible for the section investigating the integrated haemodynamic effects of drugs in experimental animals.

Applicants should hold an advanced degree in science, medicine or veterinary medicine and have appropriate experience in cardiovascular pharmacological or physiological experimental research. Documented ability to conduct independent experimental work on integrated cardiovascular control mechanism will be required. Prior knowledge of Swedish is not necessary.

Cardiovascular research at Haessle is conducted by teams working in close cooperation with internal and external specialists and is concentrated on pharmacodynamic studies in the fields of hypertension, angina, cardiac failure and cardiac arrhythmias. We provide excellent opportunities to develop and maintain international scientific contacts, as studies on basic cardiovascular mechanisms and drug action are conducted in parallel with drug development. Furthermore, we work in very close contact with University based research groups, particularly at the University of Gothenburg.

Haessle laboratories have excellent facilities for experimental work, including computer based control and data acquisition systems for integrated haemodynamic studies. Our laboratories are situated in Molndal, just outside the city of Gothenburg on the west coast of Sweden. The surroundings of the city are noted for their scenic attractions and the area provides ample opportunities for those interested in cultural events or outdoor pursuits at all times of the

ASTRA/Haessle.

TECHNICAL EDITOR WRITER - PROOFREADER **BRUSSELS, BELGIUM**

Here is an opportunity for a young scientist to join a small dynamic consulting company where rapid advancement is possible for a real producer. We need a medically oriented science graduate who has excellent communication skills to edit, rewrite and check our reports for English, logic mathematics and accuracy. The ideal age range is 24 to 34 and the location is Brussels, Belgium. The salary will be competitive and will be based upon age, relevant qualifications and experience. We will pay moving expenses. Please send C.V., two references and your telephone number.

ROBERT S. FIRST, INC. 19A Avenue Marnix, 1050 Brussels, Belgium. ≧

The University of Wollongong DEPARTMENT OF BIOLOGY

Lecturer in Ecology

(Limited term appointment of 2 years)

The appointee will be responsible for a third year course in Ecology and will be expected to contribute to other courses in the biology syllabus. Applicants should possess a higher degree and preference may be given to a candidate with postgraduate experience in Ecology. It expected that the appointee should take up the appointment on 1st February, 1982. A tenurable lectureship in this field may be advertised towards the end of 1983. Further information may be obtained from Professor A.D. Brown, Chairman, Department of

Commencing salary, according to qualifications and experience will be in the range \$A19,821 \$A26,037 per annum. Fares to Wollongong for the appointee and dependents will be paid and a relocation allowance is payable. The University will consider contributing to the cost of repatriation on conclusion of the appointment. Applications should contain full details of qualifications, employment history, research interests, publications list, and the names and addresses of three referees and should be forwarded to the University Secretary, the University of Wollongong, Box 1144, PO Wollongong, NSW 2500, Australia. Please mark envelope 'Confidential — Appointment'. Applications close 1st September (9323)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BIOCHEMISTRY SENIOR RESEARCH **ASSISTANT**

Applications are invited from suitably qualified postdoctoral research staff with particular interests and expertise in plant tissue culture and protoplast techniques, plant virology or molecular biology to work on an SRC-funded project entitled "Virus-cell interactions and the temporal control of gene expression upon infection of tobacco protoplasts with TMV".

The post is tenable for a period of up to 16 months from 1st September, 1981 at an initial salary within the range £6,070 — £6,880 per annum.

Applications, together with the names of three referees, should be received not later than 28th August, 1981, by The Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote (9295)A ref. RV/862/N.

UNIVERSITY OF PAPUA NEW GUINEA

Applications are invited for the post of

SENIOR LECTURER/LECTURER IN PHYSIOLOGY

in the Department of Human Biology in the Faculty of Medicine. It is expected that the appointee will share in the teaching of Physiology, undertake research and be actively involved in the National Staff Development Programme. The Department of Human Biology is responsible for teaching basic medical sciences to undergraduate and postgraduate medical and dental students. Courses offered include gross anatomy, histology, embryology, neurosciences, medical physiology, biochemistry and pharmacology, A degree in physiology and or medicine and a higher qualification with teaching experience is required. Teaching and/or research experience in a developing country would be an advantage. Salaries: Senior Lecturer K17,895 pa. Lecturer Grade II K16,045 pa. Lecturer Grade I K14,195 pa. In addition, a clinical allowance of up to K2,000 pa may be payable to registrable medically qualified staff who accept some clinical responsibilities. (£1 sterling = K1.28). Medical graduates have to supply evidence of their qualifications and status for registration by the Papua New Guinea Board.

Details will be sent on application. Three-year contract; gratuity; support for approved research; rentfree accommodation; family passages; baggage allowance; leave fares after 18 months service; education subsidies; salary continuation scheme to cover extended illness or disability.

Applicants who wish to arrange secondment from their home institutions will be welcomed. Detailed applications (2 copies), including a curriculum vitae, a recent including a curriculum vitae, a recent small photograph and naming 3 referees, should be sent to the Assistant Secretary (Staffing), University of Papue New Guinea, Box 4820, University PO, Papua New Guinea to arrive no later than 16 September 1981. Applicants resident in UK should also send I copy to the m UK should also send I copy to the Committee for International Cooperation in Higher Education, The British Council, Higher Education Division, 90/91 Tottenham Court Road, London W1P 0DT. Further details are available from either address.

UNIVERSITY COLLEGE **CARDIFF**

DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for an SRC-Sponsored Postdoctoral appointment for work on Bacterial Alcohol Dehydrogenase Enzymes. The appointment will be for 3 years and the appointee will join Professor K S Dodgson's research group in Studies on the Biodegradation of Surfactants. Salary within R & A Staff Range IA £6,070 — £6,880 pa. Duties to commence 1st October or as soon as possible.

Applications, (two copies), together with the names and addresses of two referees should be to the Vice-Principal (Administration) and Registrar, University College, PO Box 78, Cardiff CF1 1XL, from whom further particulars can be obtained. Closing date 10th September 1981. Ref: 2262. (9291)A

UNIVERSITY OF WESTERN AUSTRALIA Perth

BOTANY

Applications are invited for appointment as

RESEARCH OFFICER/RESEARCH FELLOW (TEMPORARY) IN

SEAGRASS ECOLOGY

in the Department of Botany. This appointment, for twelve months in the first instance, with the prospect of continuation for a further twelve months, will be to study the ecology of seagrasses in Shark Bay, Western Australia and will be required to give attention to plant production and leaf turnover rates, at specific sites, and from these assess the significance of the seagrasses to carbon, nitrogen and phosphorus cycling in the system. The appointee will join a small interdisciplinary team working especially on carbon flux, and concerned with water movement, grazing, community structure, and contributions to sedimentation. Applicants must have a relevant degree and practical experience. A higher degree is necessary for appointment at Research Fellow level. Further information may be obtained from the Head of the Department of Botany.

Current salary ranges: Research Officer — \$A14,351 — \$A18,134 per annum; Research Fellow — \$A17,083 — \$A19,821 per annum. Some financial assistance may be available for fares and other appointment expenses.

Applications in duplicate stating full personal particulars, qualifica-tions, experience and earliest possible starting date should reach the Acting Staffing Officer, University of Western Australia, Nedlands, Western Australia, 6009 by 19th September 1981. Candidates should request two referees to write immediately to the Acting Staffing Officer. (9317)A

THE UNIVERSITY **OF LEEDS DEPARTMENT OF PLANT SCIENCES**

Applications are invited for a post of **RESEARCH FELLOW**

in Cell Recognition to join an established research group in the above Department concerned with gamete recognition systems in algae. The work will involve isolation and characterization of fertilization receptors. The appointment will be made for a fixed period of up to one year and six months. Applicants should have, or shortly expect to receive, a PhD, preferably in the area of cell biology or bio chemistry (plants or animals).

Salary within the range £6,070 to £7,290 on the IA scale for Research and Analogous Staff (£6,070 to £10,575)

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 53/18/D. Closing date for applications 3rd September 1981. (9331)A

LINCOLN COLLEGE Canterbury, New Zealand

LECTURER/SENIOR LECTURER IN ANIMAL **SCIENCE**

(Growth and Development)

The Council of Lincoln College, University College of Agriculture, Canterbury, New Zealand, invites applications for appointment to the position of Lecturer/Senior Lecturer in Animal Science (Growth and Development) in the Animal Science Department within the Animal Sciences Group.

Applicants should hold a degree in Agricultural Science or its equivalent and postgraduate experience in the field of growth and development in animals. The appointee will be expected to contribute to the teaching programme of animal science to students at degree and postgraduate levels, and to contribute to the research programmes of the department in the fields of animal nutrition and disease and sheep

The successful candidate will be appointed as Lecturer or Senior Lecturer at a salary commensurate with his/her qualifications and experience. Current academic salary scales are: Lecturer NZ\$19,140 — \$23,520; Senior Lecturer NZ\$24,110 \$27,589 Bar — NZ\$30,035.

Travel and removal expenses will be reimbursed to specific limits. New Zealand Government Superannuation will be available.

Conditions of Appointment giving further details of this position may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H0PF, or from the Registrar of the College.

Applications close on 16 October 1981. (9269)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified persons for appointment to the following positions:

RESEARCH SCHOOL OF EARTH SCIENCES

Fellow in Mineral Physics

An appointment is sought in the Petrophysics Group in the field of mineral physics, specifically in elastic and anelastic properties of rocks and minerals. The successful applicant will be expected to be responsible for research in this area and in particular to develop high pressure, high temperature experimental studies relevant to the velocities and attenuation of seismic waves in rocks. Previous experience is essential. The laboratory is well-equipped for work at ultrasonic frequencies and equipment is being built for seismic frequencies

CLOSING DATE: 30 September 1981.

RESEARCH SCHOOL OF PHYSICAL SCIENCES

Professorial Fellow in Nuclear Physics

The Department of Nuclear Physics carries out work in nuclear structure physics and has an academic staff of 18 headed by Professor J.O. Newton, FAA. At present the principal fields of study are heavy ion included Coulomb excitation and reactions, including fusion, fission and transfer, and high angular momentum phenomena through heavy ion, xn reactions. The major accelerator is the 14UD pellertron tandem (14 MV terminal). An Enge splitpole spectrometer, equipped with focal plane detector, is available. The successful candidate will be expected to provide leadership in the first of these fields. Appointment will take effect from early 1982. CLOSING DATE: 30 September 1981.

Senior Fellow/Fellow in **Astrophysics**

The Mount Stromlo and Siding Spring Observatories (Director: Professor D.S. Mathewson) has its main lines of research on the evolutionary problems in global clusters, the interstellar medium, galactic structure, the Magellanic Clouds, external galaxies and radio sources. Applicants should be in the field of observational extragalactic astronomy. Appointment will take effect from early 1982. CLOSING DATE: 31 August 1981, or as soon as possible thereafter.

Postdoctoral Fellows

A number of Postdoctoral Fellowships are available in the Research School of Physical Sciences. In addition to the above, the School has Departments of Applied Mathematics, Engineering Physics, Mathematics, Solid State Physics, Theoretical Physics and the Plasma Research Laboratory and the Atomic and Molecular Physics Laboratories, the latter comprises three units — the Diffusion Research Unit, the Electron and Ion Diffusion Unit and the Ultraviolet Physics Unit. Applicants should hold, or expect to have completed by mid-1982, a PhD degree or equivalent qualification and normally be under the age of 30 at the time of application. Appointments will take effect from mid-1982 and will be for two years only. CLOSING DATE: 30 September 1981.

Salary on appointment will be in accordance with qualifications and experience within the ranges: Professorial Fellow \$A38562 p.a; Senior Fellow \$A30994-\$36125 p.a; Fellow \$A23104-\$30952 p.a; Postdoctoral Fellow — a fixed point within the range \$A19821-\$25871 p.a. Present exchange rates are: \$A1 = £Stg.0.60; \$US1.14.

Appointment, unless otherwise stated, will be: Professorial Fellow immediately to retiring age; Senior Fellow/Fellow initially for 5 years with the possibility after reviewing of reappointment to retiring age.

Reasonable travel expenses are paid and assistance with housing is given for an appointee from outside Canberra. Superannuation benefits are available for applicants eligible to contribute. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain the further particulars from the Registrar, PO Box 4, Canberra ACT 2600, Australia, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF before submitting applications.

(9318)A

Drug Discovery GRADUATE BIOCHEMIST

Hoechst, one of the largest pharmaceutical companies in the world, seeks a Biochemist to work in its modern research laboratories at Milton Keynes.

The position will be suitable for a graduate in biochemistry with an interest in the biological evaluation of compounds and, ideally, possessing 2-3 years industrial experience associated with the use of in vitro biochemical procedures

The person, male or female, whom we select will have the opportunity to play an important role in a multi-disciplinary team of biochemists. pharmacologists and synthetic chemists seeking to identify potential drugs with new modes of action.

Salaries and conditions are of the high order to be expected from a world leader and include a contributory pension scheme with free life assurance. free membership of PPP, subsidised staff restaurant, flexitime working and a generous allowance for relocation where appropriate.

Accommodation for rent or for purchase is available in the new town of Milton Keynes.

Please write or telephone for an application form to: Adrian Forrest. Personnel Department, Hoechst UK Limited, Walton Manor, Walton, Milton Keynes, Bucks. Tel: Pineham 5068.

DEPARTMENT OF ANATOMY Applications are invited from a **GRADUATE**

in biomedical sciences for the post of Research Assistant, Department of Anatomy. The successful applicant would join a small research team investigating the role of the nervous system in birth. No previous experience is necessary but a basic knowledge of nervous physiology would be beneficial. The post is supported by the Medical Research Council for three years. Starting salary £5,285 per annum.

Applications, including cv and names of two referees, should be sent to Dr A J S Summerlee, School of Veterinary Science, Park Row, Bristol BS1 5LS by 21st August, 1981. For further information please telephone Bristol (0272) 24161 ext 616, mornings only.

THE ROYAL SOCIETY GUEST RESEARCH FELLOWS

The Council of the Royal Society invites applications for the support of Guest Research Fellows. The object of this scheme, established in 1980, is to assist outstanding leaders in research in the United Kingdom to invite guests of proven ability from overseas to come and work with them for periods of at least four months and not exceeding two years. The aim is to meet the research needs of an individual through international collaboration and the emphasis in selection will be on the abilities and field of research of applicants.

Applicants (who must be working in laboratories in United Kingdom) should provide:

(a) An outline in not more than 1000 words of their present research and their proposals for developing it, together with a brief curriculum vitae (including date of birth and nationality) and list of their last six major publications.

(b) A statement explaining why their research would be significantly assisted by the presence of a Guest Research Fellow or Fellows. Initially it is not essential for applicants to name the person it is proposed to invite, but they should state clearly why international collaboration is needed. This may or may not involve identifying the laboratory from which the Guest Research Fellow will come

(c) The proposed dates of the visit with an estimate of costs and an indication of likely support from other sources. Royal Society support may include a basic maintenance allowance related to university lecturer scales, one return air fare and an additional one if the visit is for a full academic year or longer, and other expenses such as local travel and special research expenses.

(d) The names of two referees external to each applicant's group.

Applications should be made by letter addressed to the Executive Secretary (CRF/UMAM), The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, and be received not later than 30 September 1981.

(9301)A

FRESHWATER BIOLOGICAL ASSOCIATION BIOMETRICIAN/ STATISTICIAN

required for Windermere Laboratory to initiate research in biometry as applied to pupulation dynamics of benthos, plankton and fish, sampling freshwater organisms and chemical/physical variables and experimental studies in collaboration with biologists and chemists. Minimum of 2.1 honours degree in statistics/biometry/mathematics or science degree plus statistical training or experience. Conditions analogous to HSO/SSO in Civil Service, starting salary between £6,075 and £7,644 pa.

Full details: Secretary, FBA, The Ferry House, Ambleside, Cumbria LA22 0LP (096 62 2468). Closes 7 Sept. (9314)A

UNIVERSITY OF PAPUA NEW GUINEA

Applications are invited for the post of

SENIOR LECTURER/ LECTURER IN PHYSICS (Electronics and General Physics)

tenable from January 1982. The appointee will be expected to teach undergraduate courses in electronics and related topics, and to share in teaching introductory Physics. Applicants should preferably have teaching experience in these areas. The Department has a well equipped electronics workshop and has research activity in upper atmosphere physics, agricultural meteorology, thunderstorms and geomagnetism An interest and experience of one of these, while not essential, will be considered and advantage.

Salaries: Senior Lecturer K17,895 pa. Lecturer Grade II K16,045 pa. Lecturer I K14,195 pa. (£1 sterling = K1.28). Three-year contract; gratuity; support for approved research; rent-free accommodation; family passages; baggage allowance; leave fares after 18 months service; education subsidies; salary continuation scheme to cover extended illness or disability.

Applicants who wish to arrange secondment from their home institutions will be welcomed. Detailed applications (2 copies), including a curriculum vitae, a recent small photograph and naming 3 referees, should be sent to the Assistant Secretary (Staffing), University of Papua New Guinea, Box 4820, University PO, Papua New Guinea to arrive no later than 15th September 1981. Applicants resident in UK should also send 1 copy to the Committee for International Cooperation in Higher Education, The British Council, Higher Education Division, 90/91 Tottenham Court Road, London W1P 0DT. Further details are available from either address.

(9309)A

MANCHESTER AREA HEALTH AUTHORITY (TEACHING) South District CHRISTIE HOSPITAL AND

CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE JUNIOR B TECHNICIAN

to work on the measurement of steroid hormone receptors in breast cancer. The successful applicant will join a team studying this disease and will be responsible for the routine assay of clinical samples. Previous experience in steroid receptor analysis or radioimmunoassay would be an advantage but is not essential.

Salary dependent upon qualifications and experience. Day release for further study would be granted.

For an application form please apply to the Sector Administrator, Christie Hospital and Holt Radium Institute, Wilmslow Road, Withington, Manchester M20 9BX. Tel: 061-445 8123 ext 206. Closing date: 4th September, 1981.

(9313)A

Synthetic Organic Chemist

Carbohydrate Research

This is an outstanding career opportunity for an innovative and highly self-motivated research specialist at the newly established Lord Zuckerman Research Centre, set-up by Cadbury Schweppes on the campus of the University of Reading, one of Europe's leading centres of food science and technology.

The Centre, a major investment vital to the company's future growth, is responsible for fundamental research into projects relevant to Cadbury Schweppes' business as a whole and for new projects which fall outside the scope of the operating Divisions

The successful man or woman will undertake a major project and will be given every opportunity to develop and progress, both personally and professionally.

Applicants should have a good first degree in chemistry, ideally followed by a PhD, plus at least 5 years' proven experience in synthetic carbohydrate chemistry.

The salary and benefits are extremely competitive and will reflect the importance we attach to this position.

Please write with brief personal and career details to Mrs P M Carvosso, Personnei Department, Cadbury Schweppes Limited, Leconfield House, Carzon Street, London WIV 7FP. (9335)A

Cadbury Schweppes

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF ANATOMY AND EMBRYOLOGY TECHNICIANS

required to work in the research group under the direction of Professor G Burnstock

Grade 3: required to work on a three-year grant-supported project involving several techniques. Experience in biochemistry, histology, electrophysiology or electronmicroscopy would be advantageous. Starting salary £4,933 pa plus London Weighting £1,016. Quote reference FB.5.

Grade 6: with experience in biochemical assays to work in established techniques for the estimation of neurotransmitters and related enzymes and to take part in the development of new assays. Will be required to assist in the routine maintenance of a neurochemistry laboratory. This post is grant-supported and is for a period of one year in the first instance with the possibility of renewal. Starting salary £6,532 pa plus London Weighting £1,016. Quote reference FB.6.

Applications, together with curriculum vitae and the names of two referees to Personnel Officer (Technical Staff), University College London, Gower Street, London WC1E 6BT. (9292)A

THE UNIVERSITY OF SHEFFIELD CASE STUDENTSHIP IN THE DEPARTMENT OF PHYSICS

Applications are invited from graduates with a Class I or III honours degree in physics, materials science or electronic engineering, for a SERC CASE award in collaboration with AERE, Harwell, to study ion implantation in amorphous silicon and related The successful materials. candidate will join an established group in the field of amorphous semiconductors especially interested in the study of photo and electro-luminescence, using laser and related opto-electronic techniques. The objective is to clarify the relationships of impurity and defect states in amorphous materials. The group collaborates actively with a number of workers in the device field, interested, for example, in solar cells and large area displays. The CASE project will involve a wide range of solid state techniques with emphasis on the physics of these materials and should lead to a PhD. Starting date: 1 October 1981, Stipend: SERC postgraduate rate plus about £600 p.a. Apply to Dr T.M. Searle/I.G. Austin with cv, Department of Physics, the University, Sheffield S102TN, Quote ref R623/G, (9332)F

Shell has an immediate opportunity for a director of clinical research as the Cetus-Shell Interferon Program moves into clinical testing. This director will have overall responsibility for developing strategy, and for conducting and managing clinical studies on interferons. The clinical director will also provide advice and recommendations to the Shell and Cetus managements on all aspects of the program, including the development of *in vitro* tests for product efficacy.

Requirements: M.D. with experience in Phase I, Phase II drug development. Background in oncology/virology is advantageous.

Letter of application and curriculum vitae should be sent in confidence to: R&D Director—Interferon, Shell Oil Company, 901 Grayson, Berkeley, California 94710. (NW805)A

Equal Opportunity Employer M/F

UNIVERSITY OF OKLAHOMA

DEPARTMENT OF CHEMISTRY

CRYSTALLOGRAPHER

Applications are invited for this permanent, non-tenure track staff position to operate and maintain x-ray diffractometer (nonity cad-4) with primary responsibility for performing single-crystal x-ray structure determinations for chemistry research groups.

Salary commensurate with experience (18,000 dollars - 20,000 dollars per year). Successful applicant should have PhD or equivalent in chemical crystallography, experience in structure determination using single crystal x-ray diffraction, ability to operate and maintain an diffractometer, automatic knowledge in diffractometry and diffraction equipment, experience with mini-computer software applicable to automatic diffractometers and in writing analytical software for larger computers, ability to communicate with students and faculty about crystallographic problems, and experience in independent research, research publication in x-ray diffraction and in writing for research publications.

Positions available immediately. Send résumé and three letters of recommendation to chairman, Crystallographic Search Committee, Department of Chemistry, University of Oklahoma, 620 Parrington Oval, Norman, Oklahoma 73019 by October 1, 1981.

An affirmative action/equal opportunity employer. (NW814)A

UNIVERSITY OF MUNICH DEPARTMENT OF ZOOLOGY

C2 PROFESSOR IN DEVELOPMENTAL BIOLOGY

Applicants should have PhD, post-doctoral research and teaching experience (Habilitation or equivalent) and be fluent in German. Research interests should involve genetic or biochemical aspects of cell differentiation and pattern formation in lower eucaryotes.

Send curriculum vitae, list of publications, a short description of research interests and the names of 3 references before September 30, 1981, to the Dean, Faculty of Biology, University of Munich, Zoology Department, Luisenstraße 14, D-8000 München 2.

(W399)A

UNIVERSITY COLLEGE CARDIFF DEPARTMENT OF

ANATOMY BURSARY

Applications are invited from UK graduates for a Bursary in the above Department tenable in the first instance for one year but renewable up to a total of three years. While researching within the field of the Anatomical Sciences the incumbent would have the opportunity to work for a higher degree. Index-linked stipend of £2,460 includes a fee for limited teaching duties.

Applications, together with the names and addresses of three referees, should be forwarded to Professor J D Lever, Department of Anatomy, University College, PO Box 78, Cardiff CF1 1XL by 28th August 1981. Ref: 2260. (9339)A

SOUTH AFRICAN MEDICAL RESEARCH COUNCIL TUBERCULOSIS RESEARCH INSTITUTE

(Pretoria, South Africa)

Applications are invited from suitably qualified persons for the following two posts:

POST 1: MICROBIOLOGIST/ IMMUNOLOGIST

A vacancy exists for a Chief Research Officer to participate in research with a multi-disciplinary team consisting of bacteriologists, epidemiologists, a statistician and consulting clinicians and radiologists.

Requirements: A PhD or DSc, experience in medical microbilogy or immunology will be a recommendation

POST 2: BIOLOGIST/DATA ANALYST

A Research Officer is required to participate in and later manage projects in connection with health surveys, disease risks and the analysis of data obtained from medical and paramedical services.

Requirements: Msc, BSc (Hons) graduate or BSc with experience in one of the biological fields such as microbiology, physiology, zoology, etc with a knowledge of data analysis. Computer programming ability would be useful (but is not essential).

Further particulars and application forms are obtainable from the South African Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE. Tel: 242 1766.

General: The MRC is nationally responsible for medical research in South Africa in terms of an Act of Parliament. Its head office is near Cape Town with research institutes and laboratories situated throughout the country.

The MRC offers a five-day week, an academic environment, excellent opportunities for research and further study, group life insurance scheme, pension and medical schemes, a service bonus, generous vacation and sick leave and a housing subsidy for those who qualify.

(9303)A

UNIVERSITY OF EAST ANGLIA Norwich POSTDOCTORAL SENIOR RESEARCH ASSOCIATE

required in the School of Biological Sciences to investigate genetics of mating recognition by song within and between sibling species of grasshopper and its relation to allozyme differences. An interest in quantitative genetics is desirable but not essential. The appointment is supported by a 3 year SERC grant and salary in the range £6,880 — £7,700 per annum.

Applications including a curriculum vitae and naming two referees should be sent to Dr G M Hewitt, Biological Sciences, UEA, Norwich NR4 7TJ by 28th August, 1981. (9342)A

UNIVERSITY OF FORT HARE Republic of South Africa PROFESSOR AND HEAD OF THE DEPARTMENT OF

MICROBIOLOGY
Applications are invited from suitably qualified candidates for the above post.

Minimum requirements: A Doctorate and preferably teaching experience. Candidates must be able to lecture through the medium of English.

Assumption of duty: As soon as possible. Closing date for applications: 4th September 1981.

General: The University of Fort Hare is situated near Alice in the Ciskei. Persons who are not South African Citizens can only be appointed on contract basis, which is usually for an initial period of three years renewable thereafter for further three year periods.

Salary: Professor — R17,100 × R750 — R18,600 × R900 — R22,200.

Additional Fringe Benefits: The following benefits are available subject to certain conditions: Group life assurance; medical aid; pension scheme; service bonus; territorial allowance; generous leave and sick leave benefits and generous assistance towards university training of employees' children in the Republic of South Africa.

Applications including a complete curriculum vitae and the names and addresses of at least three referees, should be addressed to: The Staff Officer, University of Fort Hare, Private Bag X1314, Alice 5700, Republic of South Africa. Telephone: 281 Alice, Telegraphic address: Unifort Alice. (9302)A

POST DOCTORAL POSITION

To study structure/function relationships in contractile proteins. Experience in protein modification and characterisation desirable.

Send curriculum vitae and two letters of reference to Dr M Burke, Department of Biology, Case Western Reserve University, Cleveland, Ohio 44106. (NW813)A

UNIVERSITY OF THE WITWATERSRAND Johannesburg DEPARTMENT OF BOTANY SENIOR LECTURER/ LECTURER IN PLANT **PHYSIOLOGY**

Applications are invited from suitably qualified persons, regardless of sex, race, colour or national origin, for appointment to the above

Preference will be given to candidates with specialist interests in one or more of the following areas; physiology of growth substances and plant growth and development; ecophysiology; and plant water relations, as well as a good general botanical background in order to participate in the first year teaching programme.

Duties are to be assumed on 1st Feburary 1982, or as soon as possible thereafter.

The salary attached to the appointment will be in the ranges: Senior Lecturer: R14,370 — R20,850 pa. Lecturer: R10,995 — R19,230 pa.

The initial salary and level of appointment will be determined according to the qualifications and experience of the successful candidate. An annual service bonus in accordance with existing Government regulations is also payable.

Interested persons are invited to obtain the information sheet relating to this post from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WCIV 7HE, or from the Registrar (Staffing), University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa 2001, with whom applications should be lodged by 30 September 1981. (9306)A

UNIVERSITY OF LONDON Institute of Neurology **DEPARTMENT OF** NEUROCHEMISTRY POST-DOCTORAL WORKER (Grade 1A)

required in a team working on metabolism and role of 5-HT (and related topics) and supported until July 1984 by MRC programme grant. Experience in at least one of the following fields essential: neurochemistry, neuropharmacology, behaviour. The successful applicant will mainly study the effects of hormonal and nutritional status on transmitter metabolism and on behaviours due to transmitter release. Initial salary on scale £7,037
— £11,542 including London Allowance.

Applications with CV and names of two referees to Professor G Curzon, 33 John's Mews, London WC1, by 15 September 1981

(9325)A

THE LINNEAN SOCIETY OF LONDON

PLANT TAXONOMIST

Applications are invited for the post of Plant Taxonomist to undertake the compilation of a critical catalogue, for eventual publication, of the type specimens of Linnaean plant species. The work, which will result in a much needed source of reference for taxonomic botanists throughout the world, will provide an exceptional training opportunity in formal taxonomy and nomenclature.

The project is supported by a grant from the SRC and will be based in the Department of Botany, British Museum (Natural History), under the supervision of Professor W T Stearn and Dr N K B Robson. Employment will be on the basis of a three-year contract, with the possibility of further extension.

Starting salary will be £6,986 (under review) plus £1,016 London Weighting, and work will commence at the earliest possible date after 1st October 1981. The successful candidate will probably have a degree in Botany or in some related field, but graduate qualifications are not essential. Practical experience as a taxonomist dealing with day to day problems in nomenclature would be a special recommendation. Background experience in librarianship and bibliography might also be

Applications with full curriculum vitae and two references should be sent by 7th September 1981 to: The Executive Secretary, The Linnean Society of London, Burlington House, Piccadilly, London WIV OLQ. Further information on the project can be obtained from Dr Robson or Mr Cannon at the British Museum (Natural History). Tel: 01-589 6323. (9329)A 01-589 6323.

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF GENETICS **POST GRADUATE** RESEARCH ASSISTANT

Applications are invited for this MRC-funded post tenable for 3 years from 1 October, 1981 to work on the biochemical and genetic analysis of in vitro genetic recombination in bacterial viruses under the supervision of Professor D A Ritchie. Candidates should have a good Honours degree in Biochemistry, Genetics or Microbiology and an interest in microbial genetics. There will be an opportunity to register for a higher degree.

Initial salary £5,285 per annum.

Applications, together with the names of three referees, should be received as soon as possible. The Registrar, The University, PO Box , Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/860. (9290)A

Graduate Chemist

£8,959 - £9,811

for the New River Head Laboratories of the Directorate of Scientific Services. You will be concerned with the analysis of trace organic compounds in water and you should have proven experience of organic analysis in general and of modern chromatography and related techniques in particular. Experience in gas chromatography/mass spectrometry would be an advantage.

Much of the work to be carried out forms part of the Authority's research programme and together with other duties, will be under the direction of the Manager, Metropolitan Water Services.

The post is open to men and women and application forms may be obtained from the Regional Manager (Manpower), New River Head, London EC1R 4TP telephone 01-837 3300 ext 2024. (9307

DARTMOUTH MEDICAL **SCHOOL**

Hanover, New Hampshire **IMMUNOLOGY PROGRAM** POSTDOCTORAL RESEARCH ASSOCIATE

Two postdoctoral positions are open as of January-July, 1982 for research on T-cell growth factor and the regulation of T- and B-cell function. Experience in cellular immunology, long-term culture of T-cells, biochemistry, and/or hormone-receptor interaction is desirable. The appointment will be for a minimum of two years. Salary is negotiable depending on experience.

Send curriculum vitae and two letters of reference to: Dr Kendall A Smith, The Basel Institute for Immunology, 487 Grenzacherstrasse, CH 4058 Basel, Switzerland.

An Equal Opportunity/Affirmative Action Émployer. (NW807)A

UNIVERSITY OF BRADFORD RESEARCH ASSISTANT in Chemical Engineering (fixed-term appointment -3 years)

Applications are invited from graduates in Science, Electrical Engineering or Chemical Engineering to work as part of a team on a project concerned with liquid separation in electrostatic fields. The appointment is supported by the SERC. Opportunity to register for a higher degree. Starting salary, £5,285 pa. Superannuable.

Further particulars and application forms are available from the Personnel Secretary, University of Bradford, West Yorkshire BD7 1DP. (Ref: RA/CHE/SERC/3/N). Informal enquiries to Dr P J Bailes, School of Chemical Engineering (9312)A

HILL FARMING RESEARCH OFGANISATION

Scientific Officer/Higher Scientific Officer

Applications are invited for a Scientific Officer/Higher Scientific Officer to join a research group working on the nutrition of hill and upland beef

The successful applicant will be expected to take up an innovative role within a small group working in the Beef Production Section. This research programme is largely concerned with the effects of nutrition on the components of cattle production. There will be opportunities for studies of both juvenile and adult animals, to engage in metabolic investigations and to become involved in work on systems research.

Qualifications: First or upper second class honours degree or equivalent in a relevant branch of science, preferably including Ruminant Nutrition or a related subject and some relevant post qualifying experience. At least two years relevant post qualifying experience required for

Salary: SCIENTIFIC OFFICER, according to qualifications within the scale £4,809 to £6,480.

HIGHER SCIENTIFIC OFFICER, commencing £6,075. The scale is from £6,075 to £7,999.

The salary scales are at present under review. Other Conditions: Non contributory Superannuation Scheme.

Scientific Officer – 20 days annual leave
Higher Scientific Officer – 22 days annual leave
Further particulars and application forms from the Secretary,
Hill Farming Research Organisation, Bush Estate, Penicuik,
Midlothian EH26 OPY to whom they should be returned not later than 11th September 1981.

M.R.C. CLINICAL RESEARCH CENTRE (NORTHWICK PARK HOSPITAL) **Watford Road** Harrow Middx HA13UJ

Senior Technician

On 1st October 1981, following a retirement, a vacancy will arise for the post of Senior Technician in the Division of Anaesthesia. Apart from the administrative responsibilities of Senior Technician; the successful applicant will be expected to participate in some aspects of the research work, which is broadly based within the field of anaesthesia and includes hyperbaric studies.

Applicants should have substantial experience in physics, electronics, neurophysiology or neurochemistry and be qualified to HNC/degree level or equivalent in an appropriate subject.

Salary/£6,656 to £8,622 inc L.W. dependant upon qualifications and

For application forms and further details, please write to Miss J. Cottam Personnel Section, quoting ref 101/2/3835.

Closing date 3 weeks from appearance of this advertisement.

(9297)A

IMMUNOLOGIST/ IMMUNOCHEMIST

Staff research position available for experienced researcher with PhD or MD interested in applying new technologies to the study of human disease

Experience with monoclonal antibody production and isolation of cellular antigens is desirable. Send CV and references to:

Dr. Robert Colvin, Immunopathology - Cox 5, Mass. General Hospital, Boston, MA 02114. (NW798)A

POST DOCTORAL RESEARCH ASSOCIATE **POSITION**

Available immediatly for candidate with a demonstrated interest and technological expertise developmental and molecular biology. Experience in hematopoietic stem cell growth in vitro desirable. Excellent research opportunity in the area of haemoglobin synthesis in man and baboon model systems. Salary negotiable and competitive.

Candidates would be employee of the University of Illinois. Career posibilities. Send curriculum vitae and names of three referees to: Doctor Joseph De Simone, Haemotology Research Laboratory, Veterans Administration, West Side Medical Centre, 820 South Danien Avenue, Chicago, Illinois 60612. An Affirmative Action/Equal Opport-(NW809)A unity Employer.

UNIVERSITY OF CAPE TOWN

Junior Lecturer in Geology

Applications are invited for the above post, vacant as from 1st January 1982. Appointment, according to qualifications and experience, will be made in the salary range R6 810 — R8 970 per annum.

The successful candidate will be required to give lectures and practicals carrying a total contact load of approximately 100 hours, either spread throughout the year or concentrated in one semester. The position is suitable for a graduate who wishes to engage in independent research in the department, or for a recent graduate wishing to register in the department towards a higher degree. Appointment is made on a year-to-year basis, and is normally renewed annually.

While candidates with special interests in any of the subdisciplines of geology will be considered, and selection will be on merit, preference will be given to candidates with experience and interest in sedimentology and/or the economic geology of sedimentary deposits.

Applicants should submit a curriculum vitae, stating present salary, research interests and publications, when available if appointed, and the names and addresses of three referees.

Further information should be obtained from the Head, Department of Geology, University of Cape Town, Rondebosch, 7700. Closing date 12th October 1981 but late applications may be accepted. Please quote reference number (AC.7).

The University's policy is not to discriminate in the appointment of staff on the grounds of sex, race or religion. Further information on the implementation of this policy is obtainable from the Registrar. (W400)A

UNIVERSITY OF FORT HARE Republic of South Africa PROFESSOR/SENIOR LECTURER IN MICROBIOLOGY

Applications are invited from suitably qualified candidates for the above post.

Minimum requirements: Doctorate and preferably teaching experience. Candidates must be able to lecture through the medium of English.

Assumption of duty: As soon as possible. Closing date applications: 25th September 1981.

General: The University of Fort Hare is situated near Alice in the Ciskei. Persons who are not South African Citizens can only be appointed on contract basis, which is usually for an initial period of three years renewable thereafter for further three year periods.

Salary: Professor - R20,040 - $R20.850 \times R900 - R26.250$.

IN THE FACULTY OF

PROFESSOR IN BIOPHYSICS

is vacant

The candidate for this post will be expected to devote his research activites to experimental membrane biophysics as his main effort. His teaching should be focussed on courses, which enable graduate students in physics, chemistry, computer sciences and mathematics to acquire knowledge in biophysics. Applicants should be proficient in German.

Applications including a curriculum and a list of publications should be sent before October 30th, 1981, to the dean (Dekan) of the Faculty, Altenbergerstr. 69, A-4040 Linz, Austria. Dean Prof Dr Bruno (W397)A Buchberger.

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London) A CHIEF TECHNICIAN

is required to work in the Anatomy Department. The successful candidate will supervise technical services and the technicians in the department and will also be responsible for the Anatomy laboratories. The Department of Anatomy is currently situated in Hunter Street, but will be moving to new accommodation in the Medical School Building at Hampstead in the near future.

Salary on scale £8,159 - £9,385 inclusive (under review). 37 Hour week. 34 days leave including public & customary days. Interest free annual season ticket loan scheme.

Further particulars and application forms are available from the School Secretary, RFHSM, 8 Hunter Street, London WC1N 1BP or tele-phone 01-837 5385 ext 10. Closing date: 28 August 1981. Reference AD/CT. (9321)A

RESEARCH ASSOCIATE

Position available immediately for PhD to work on biochemical and physiological mechanisms in the crystalline lens in relation to cataract development. Experience in membrane or protein bio-chemistry would be most advantageous. Send Curriculum vitae and names of two references to Dr C A Paterson, Box B 205 University of Colorado Health Sciences Center, 4200 E 9th Ave., Denver, Colorado 80262. USA. The University of Colorado is an equal opport-(NW810)A unity employer.

ASSISTANTSHIPS

KING'S COLLEGE LONDON (University of London)

DEPARTMENT OF ANATOMY Applications are invited for a three year

RESEARCH **ASSISTANTSHIP**

from 1st October, 1981, funded by the Arthritis and Rheumatism Council, to investigate the mechanics of the arthritic foot and ankle joint and the influence of progressive pathological changes within the foot and ankle joint on gait. In addition to the appropriate biological background, the person appointed will be expected to have a reasonable knowledge of statistics and computing

Starting salary will be in the rage £5,285 — £6,070, depending on age and experience, plus London Weighting of £967.

Applications including a full curriculum vitae and names and addresses of 2 referees to Dr R W Soames, Department of Anatomy, King's College London, Strand, London WC2R 2LS by 28th August, 1981.

continued on page xvii

ASSISTANTSHIPS

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF CERAMICS. GLASSES AND POLYMERS

RESEARCH **ASSISTANTSHIP**

Applications are invited from men and women for the above post to study the process of transformation of nitch-like materials and single aromatic hydrocarbons to carbon by pyrolysis. The process occurs via a liquid crystalline (mesophase) the growth and coalescence of which determines the microstructure of the carbon product. The approach will be to construct pseudo-phase diagrams for the transformation after which the properties of various compositions in the different phase fields will be studied. Emphasis will be placed on the rheological properties. This project, supervised by Dr B. Rand, is financed by SRC. Tenable for 3 years from 1 October 1981 at an initial salary up to £6,880 a year depending on age and experience. An honours degree in a physical science subject and research experience (preferably to PhD level) required. Experience in carbon technology, liquid crystals or polymers rheology would be relevant. Particulars from the Registrar and Secretary, The University, Sheffield S10 2TN, to whom applications including the names and addresses of two referees, should be sent by 24 August 1981. Quote ref: R 621/G.

UNIVERSITY OF OXFORD

DYSON PERRINS LABORATORY THREE POSTDOCTORAL RESEARCH ASSISTANTSHIPS

Applications are invited for three postdoctoral research assistantships (supported by SRC) as follows:

- 1. To study stereochemical effects on nuclear spin coupling between directly bonded carbon atoms (for one year);
- 2. To develop and exploit a stopped flow laser polarimeter for heavy atom kinetic isotope effects (for one year);
- 3. To re-examine proximity ('steric') isotope effects (for two years).

Applicants should have experience in one or more of the following:

a) Synthesise with stable isotopes:b) F T nmr (posts 1 and 3);

c) Electronics (post 2).

The appointments are for one year ffrom 1st October 1981, or up to 3 to 6 months later by agreement) with post 3 being renewable for a second year. The starting salary will be in the range £6,070 to £6,880 pa (Research Support Grade 1A) plus USS,

according to age and experience.

Applications (one copy) with curriculum vitae and names and addresses of at least two referees should be sent as soon as possible to Dr M J T Robinson, Dyson Perrins Laboratory, South Parks Road, Oxford OX13QY. (9299)P

STUDENTSHIPS

UNIVERSITY OF LEEDS DEPARTMENT OF PLANT SCIENCES AN SERC (CASE) STUDENTSHIP

in conjunction with International Paint Marine Services is available for a good honours graduate in biology, microbiology or biochemistry. The investigation involves aspects of the biology and metabolism of selected diatom species, in relation to the problem

of tanker fouling.

Interested persons should contact Dr L V Evans, Department of Plant Sciences, The University, Leeds LS29JT by telephone (Leeds 31751 ext 6576), or submit a curriculum vitae to him with the names of two academic referees as soon as possible.

RESEARCH STUDENTSHIP EAST MALLING RESEARCH STATION

Applications are invited from candidates with a first or upper second-class honours degree in biochemistry on plant physiology for a studentship leading to a PhD on hormone regulation of pear fruit development.

Further details of this award, which is tenable for three years from October 1981, are available from the Deputy Secretary, East Malling Research Station, Maidstone, Kent ME196BJ. (9311)F

UNIVERSITY of Aston in Birmingham, Department of Biological Sciences — Fish Culture Unit. Research Studentship. Applications are invited from good Honours graduates in Biology, Biochemistry and Physiology, for a 3-year Research Studentship sponsored by the Tropical Products Institute. The project is for research on "The effects of the protein quality of feed ingredients of tropical origin on the growth and carcase characteristics of Tilapia". The general conditions for the Research Studentship are Analogous to those of the Science Research Council. Application forms are available from The Secretary, Department of Biological Sciences, University of Aston, Gosta Green, Birmingham B4 7ET and must be returned completed by Friday September 1981. (9343)F

ANNOUNCEMENTS

STANFORD UNIVERSITY **ANNOUNCEMENT**

Stanford University, in cooperation with the University of California, announces that patent licenses are now available on a non-exclusive basis for the genetic engineering inventions of Dr Herbert W Boyer of the University of California and Dr Stanley N Cohen of Stanford University (US Patent No 4,237,224 issued December 2, 1980 and pending US Patent Application No 959,288 filed November 9, 1978). gratefully acknowledge the financial support of the American Cancer Society, the National Institutes of Health and the National Science Foundation to the fundamental research programs from which the inventions resulted.

Farned royalties for end products are scaled, based on sales volume, from 1.0% to 0.5% of sales, for annual sales over \$10 million. To encourage companies to license early, a multiple of the minimum annual fees of \$10,000 can be credited against earned royalties. For example, for licenses signed before 15 December 1981, licensees may credit \$50,000 (against earned royalties otherwise payable in a future year) for each \$10,000 annual fee paid before commercial sales begin or 1987, whichever occurs first. Terms for licenses signed after 15 December 1981 will be less favorable to the licensee.

The license also requires that licensees specifically express intent to comply with the physical and biological containment standards of the NIH guidelines for recombinant DNA research.

Pursuant to 19USC337a, patent licenses are applicable to sales in the US of products derived from practice of methods of the patents outside of

The Universities intend to use royalty revenue for educational and research purposes which, in turn, may result in yet other scientific advances for public use and benefit.

For a copy of the license agreement, write to the Office of Technology Licensing, 105 Encina Hall, Stanford University, Hall, Stanford, California 94305.

OF BRISTOL
H H WILLS PHYSICS LABORATORY
POST-DOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a threeyear post-doctoral assistantship by the Science Research Council to investigate the isotopic dependence of neutron scattering lengths for a range of elements. This is a collaborative programme with the University of Munich and access to facilities at FRM Reaktorstation Garching will be made available to the successful candidate.

We are seeking a postgraduate with a good background in materials science. Experience in electron microscopy would be particularly useful. A knowledge of low energy nuclear physics or neutron scattering techniques is not required as training in these areas will be given.

The post will provide a good opportunity for a young physicist to broaden his or her experience. The starting salary will be at point 3 (£6,880) on the RA/1B scale, and the position is available from 1st October 1981.

Applications, which should Applications, which should include the names of two referees, should be sent to Professor J E Enderby, H H Wills Physics Laboratory, University of Bristol, Royal Fort, Tyndall Avenue, Bristol BS8 ITL. (9328)P

GRANTS and SCHOLARSHIPS

ARMAGH OBSERVATORY Armagh, Northern Ireland Applications are invited for a **SCHOLARSHIP**

at Armagh Observatory from candidates holding a good honours degree in physics, or astronomy, or a closely related field. Excellent opportunities for working towards a PhD thesis are being offered.

Applications stating qualifications, research interests, and names of two referees should be received not later than September 30, 1981 by the Secretary, Armagh Observatory, Armagh, N Ireland BT61 9DG, from whom further particulars may be obtained. (9298)H

IMPERIAL CANCER RESEARCH FUND Research Studentship (Bursary)

Applications are invited from recent honour graduates for a Bursary in the Transcription Laboratory to study the molecular biology of the DNA tumour virus polyoma.

The award, for full time studies leading to a higher degree (PhD) will be tenable for three years with a non-pensionable grant of £4,140 a year (subject to tax) and in some cases additional allowances. Candidates should have a first or upper second class honours degree in one of the biological sciences if they are UK graduates, but non-U.K. residents are not necessarily excluded. A strong background in molecular biology will be important and some training in recombinant DNA techniques would be particularly desirable.

For further information telephone Dr R. Kamen (01-242 0200 ext 277). Application forms are available from The Personnel Officer, Imperial Cancer Research Fund, Lincoln's Inn Fields London WC2. Tel. as above ext 305. Completed application forms should reach the Fund no later than 1st September 1981.

(9294)H

FELLOWSHIPS

MULTIPLE SCLEROSIS RESEARCH TRAINING **FELLOWSHIP**

Tenure 3 years. To work in the Neurovirology Unit, Department of Neurology, St. Thomas' Hospital, London SEI 7EH. On "Mechanisms of pathogenesis of CNS virus diseases with special reference to demyelination". Current research is related to the virology, immunology, pathology, electron-microscopy and biocemical abnormalities associated with these infections. Applicants should apply by October 1, 1981 to Dr H E Webb giving a Curriculum Vitae with photograph and 2 referees. Salary will be by arrangement according to age and experience up to £8,000 a year. Anticipated starting date. (9333)E February 1, 1982.

UNIVERSITY OF WARWICK

POSTDOCTORAL FELLOWSHIP IN **MOLECULAR VIROLOGY**

Applications are invited from microbial geneticists, virologists and other suitably qualified candidates to work in the Department of Biological Sciences on an MRC funded project concerned with the molecular cloning of rotaviruses. Candidates with recombinant DNA experience are particularly welcome to apply. The appointment is for three years and is available immediately.

Salary in the range £6,070 to £10,575 pa. For arther details please write direct to Dr M A McCrae, Department of Biological Sciences.

Written applications should include a curriculum vitae and the names and addresses of two referees to the Academic Registrar, University of Warwick, Coventry CV4 7AL quoting Ref No: 51/A/81/0. Closing date for receipt of applications 28th August, 1981. (9338)E

POSTDOCTORAL FELLOWSHIP IN CARDIAC CELLULAR **ELECTROPHYSIOLOGY**

Two traineeships are available (2-3 years) to study (1) action potential conduction mechanisms and intercellular junctional coupling and (2) membrane ionic conductance mechanisms in isolated cell and tissue cultured model cardiac prepara-tions. Conventional microelectrode methods, voltage clamp and patch-electrode techniques will be employed as well as impedance/ noise analysis. Training will be provided in these techniques and in the preparation and manipulation of isolated cell systems. Support and excellent facilities are provided through an active interdepartmental program project.

Send curriculum vitae and names of three professional references to: Dr R L DeHaan, Department of Anatomy, Emory University School of Medicine, Atlanta, GA 30322. Emory University is an Equal Opportunity/Affirmative Action (NW811)E Employer.

UNIVERSITY OF CAPE TOWN

Research Fellowships

The University of Cape Town invites applications for Post-Doctoral Fellowships to be held at the University of Cape Town.

The Fellowships are tenable for 12 months and the stipend attached to the Fellowship is R16,000. Successful candidates from abroad will receive an additional travel grant up to a maximum of R1,500. There is no restrictions to any particular field of research.

Applications must include full details of the applicant's research programme in addition to a full curriculum vitae and the names of two referees to whom the University may refer. The policy of the University is not to discriminate in the appointment of staff on the grounds of sex race, colour or national origin. The dates at which the successful candidates will be expected to take up their duties are flexible and can be arranged to suit the special circumstances of the candidate.

Closing date for the receipt of applications is 30 September 1981.

Applications (quoting ref. number AC7) should be addressed to the Chief Administrative Officer, Research Administration, University of Cape Town, Private Bag, Rondebosch, 7700, South (W402)E Africa.

UNIVERSITY OF WESTERN AUSTRALIA Perth

UNIVERSITY RESEARCH FELLOWSHIPS (Post-Doctoral)

Up to two Research Fellowships will be offered, to be taken up in 1982. Appointment will be for one year in the first instance with the possibility of renewal for a second year: Fellowships may be renewed for a third year, but only in competition with new applications. The Fellowships will be tenable in the following academic Departments for work in the broad areas stated below:

Biochemistry - Hormonal Control of Cytochrome Synthesis in Mitochrondria of Developing Rat Ovary, Medicine — Studies of Ovary. Medicine -Patterns of Disease in Migrants to Australia, Microbiology - Genetic Analysis and Modification of the Fungus Phytophthora cinnamomi. Physical and Inorganic Chemistry Theoretical Calculations of Atomic Polarizabilities using the Method of Configurational Interaction.

The Fellowships are intended for PhD graduates, or those with equivalent qualifications, who by publication and in other ways have demonstrated significant research capability. Preference will normally be given to graduates of universities other than the University of Western Australia. Salary will be within the range \$A17083 — \$A19570 per annum.

Applications in duplicate setting out full personal particulars, qualifications and experience, and the proposal for research during the tenure of the Fellowship should reach the Acting Staffing Officer, University of Western Australia, Nedlands, Western Australia, 6009 by 2nd October 1981. Candidates should request three referees to write immediately to the Acting Staffing Officer from whom any further specific information may be obtained (9330)E

IMPERIAL CANCER RESEARCH FUND POSTDOCTORAL RESEARCH **FELLOWSHIP**

Applications are invited for a three year, postdoctoral appointment in the Viral Leukaemogenesis Labo-ratory at Lincoln's Inn Fields to work on control of expression of membrane proteins during differentiation of erythroblasts transformed by avian retrovirus, in particular avian erythrobalstosis

Salary range: £7,700 to £9,750, plus London Allowance of £967 a year, with entry point according to qualifications and experience.

Further information from Dr. M. Hayman (telephone 01-242 0200 extension 448). Applications including full curriculum vitae and names and addresses of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2, by 31st Imperial Cancer August, 1981, quoting reference 121/81. (9244)E 121/81.

IMPERIAL CANCER RESEARCH FUND POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a three vear postdoctoral appointment in the joint laboratories of Tumour Virology and Viral Leukaemogenesis at Lincoln's Inn Fields to apply recombinant DNA techniques to the study of virus-induced oncogenesis. Molecular cloning of RNA tumour viruses is being undertaken to investigate, by a combination of restriction enzyme analysis, DNA sequencing and DNA transfection, the structure and function of mutant and wild type viral transforming genes and their interaction with host cell sequences in which they integrate. Salary range £7,700 — £9,750 plus London Allowance £967 a year, with entry point according to qualifications and experience. Further information from Dr. John Wyke (tel. 01-242 0200 ext 270). Applications with curriculum vitae and names and addresses of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 by 31st August, 1981 quoting reference

Improve Your Assays in Any Biochemical Procedure!

The Savant "NO BUMP" Speed Vac Concentrator/Evaporator is now standard procedure for the following and many other applications.

Achieve 100% Sample Recovery!

- HPLC sample preparation where a dried, concentrated sample is important.
- GLC sample preparation . . . as above.
- DNA sequencing evaporation of piperdine.
- PHOSPHOLIPIO separation by HPLC
 — total evaporation of Acetonitrile-Water Solvent.
- TRIETHANOL AMINE carbonate evaporation
- SOMATOSTATIN concentration by evaporation of acetic acid.
- INTERFERON purification by dialysis and evaporation of solvent phase.
- TRI-CYCLIC anti-depressant drug blood levels measured after a series of extractions and evaporations to dryness
- NEUROTRANSMITTERS such as Acetylcholine, Dopa, etc. Now include the Speed Vac Concentrator for the essential evaporation step.
- * AMINO ACID and Peptide analysis
- SUBSTANCE P concentration and assay.
- HORMONE and Enzyme assays.
- TISSUE EXTRACTS and Column eluates concentrated by "NO BUMP" solvent removal
- ELECTROPHORESIS AND CHROMATOGRAPHY is greatly improved by concentration prior to application of sample to the support medium.

British Journal of CLINICAL PHARMACOLOGY

ESSENTIAL INFORMATION AT YOUR FINGERTIPS. EVERY MONTH!

Published monthly on behalf of the British Pharmacological Society, British Journal of Clinical Pharmacology is as fast-moving as the area of science it examines:

Bridging the gap between medical professions, clinical research and the pharmaceutical industry.

Containing papers and reports on all aspects of drug action in man, in both health and disease.

Providing free copies of the proceedings of selected symposia on new methods, new drugs and new approaches to treatment, to all subscribers.

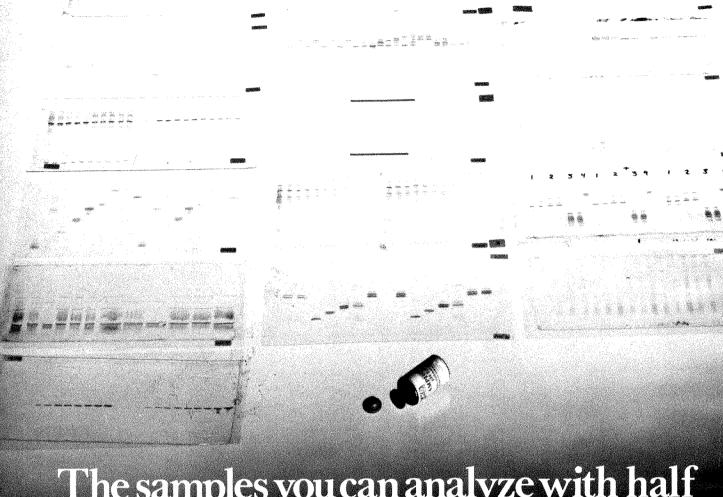

To keep up-to-date in this fast-moving area of science why not join the ever-increasing number of clinical pharmacologists all over the world who rely on the British Journal of Clinical Pharmacology as their professional journal.

ANNUAL SUBSCRIPTIONS

UK £75.00 USA/Canada US\$185 Rest of the world £89

Orders should be accompanied by remittance, cheques made payable to Macmillan Journals Ltd: Subscription Department, Brunel Road, Basingstoke, Hampshire, RG21 2XS, England.

Sample copies are also available from the same address.

The samples you can analyze with half a bottle of Ampholine

Cut your electrofocusing costs to a fraction of previous levels without sacrificing quality or resolution. Save substantial time casting, running, and staining gels as well. High performance electrofocusing lets you analyze well over 600 samples per bottle of Ampholine. And if you're struggling with an especially tight budget this year, we can help you save even more. High performance gels are cast by capillary action onto thin plastic support foils in layers a mere 0.5 to 0.25 mm thick. Because the new thin gels are cooled more efficiently, resolution-robbing thermal gradients are eliminated while run times drop to as little as 30 minutes.

Ampholine, the LKB tradename for the world's largest selling carrier ampholyte, is now available in four new pH ranges. The new ranges are specially preblended for direct use in either acrylamide or our new agarose gels and exhibit excellent conductivity and reproducibility. By switching to our new preblends, you'll save preparation time and reduce your stocking costs as well.

High performance electrofocusing is just one of a series of new and improved techniques you can perform on the Multiphor® System. For more details about this and other new kits soon to be released, contact your local LKB representative. We have offices everywhere. Or phone us today at one of the addresses listed below.

Photomacrography: easier than ever before.

WILD M400 PHOTOMAKROSKOP.

No other photographic technique today is so reminiscent of the methods of yesteryear's pioneers in photography as is photomacrography (range 1:1 to 20:1). In the past, the bellows was unwieldy, setting the image scale complicated and calculating the exposure time a long-drawnout operation. You literally had to grope for the object. Not what you would call efficient! And yet efficiency is just what is needed in science and technology where photomacrography is playing an ever more important role.

Now Wild Heerbrugg has developed a new photomacrographic system, the Wild M400 Photomakroskop. Circle No. 18 on Reader Enquiry Card.

Modern photographic technology and electronics guarantee a high degree of efficiency within the magnification range of 1:1 to 60:1. Magnification and detail can be continuously varied with the macrozoom objective 1:5. What's more, the M400 gives you binocular observation under optimum physiological conditions, an erect and laterally-correct image and a great working distance. The specimen remains in focus over the whole zoom range. The electronic control unit ensures ideal exposure time at the touch of a button, independently of camera format, film emulsion and illumination method. It's easier and better than ever before.

From DNA to RNA and beyond

These nine systems represent a major achievement in support of DNA/RNA research. They offer pretested, quality-assured sets of matched ingredients for analyzing genes and the products of their expression.

You could of course assemble the ingredients yourself, but here's what you'd likely be missing: Reliability, reproducibility, and hours of time better spent doing the research.

Call to discuss any questions you may have for our technical staff.

Nick Translation

Two exclusive systems for making consistently high specific activity probes using nick translation: dCTP, [32P]- and dTTP, [3H]-. Both systems include *E. coli* DNA Polymerase I prepared in our laboratories to ensure reproducibility. The DNase I, dNTP mixtures, stop buffer, and sterile deionized water are optimized for compatibility and stability.

Systems sufficient for either 20 or 10 reactions contain the following:

dCTP, $[\alpha^{-32}P]$ -, or dTTP, [methyl, 1', 2',-3H]-

dTTP, [methyl, 1', 2;-3H]. DNase I

DNA Polymerase I

Control Plasmid DNA (pBR322)

Deoxynucleoside Triphosphate
Mixture

Nick Translation Buffer Nick Translation Stop Buffer Deionized Water

Each lot of systems is tested with the control supercoil pBR322 plasmid DNA to ensure efficient incorporation of dCMP or dTMP into DNA, and a copy of the curve is included with your system.

Ordering information:

NEK-004 (dCTP, $[\alpha^{-32}P]$) (20 reactions, tracer in ethanol) NEK-004A (10 reactions, tracer in ethanol) NEK-004B (20 reactions, tracer concentrated in aqueous solution) NEK-004C (10 reactions, tracer concentrated in aqueous solution) NEK-005 (dTTP, $[^3H]$) (20-reaction system)

3' End Labeling

The system labels protruding ($Hae\ II$), flush ($Alu\ I$), and recessed ($Hinf\ I$) 3' termini generated from pBR322 with 3'-dATP, [α - 32 P]- (cordycepin 5'-triphosphate) in a simplified protocol similar to the procedures of Tu and Cohen. The system utilizes terminal transferase to add a single 3'-dAMP, [α - 32 P]-molecule to the 3' end of a DNA chain. The resulting labeled DNA is suitable for sequencing by the Maxam and Gilbert technique used in our new DNA Sequencing System (see next page).

The components include:

3'-dATP, $[\alpha^{-32}P]$ - (cordycepin

5'-triphosphate)

Terminal Deoxynucleotidyl

Transferase

Terminal Transferase Reaction

Buffer

Cobalt Chloride

Control Plasmid DNA Fragments

Deionized Water

Prior to shipment, all system components are subjected to a complete 3' end labeling procedure. The polyacrylamide gel used to separate the fragments is autoradiographed to assess labeling efficiency, and a copy of the autoradiogram is included with your system.

Ordering information:

NEK-009 (10-reaction system) NEK-009A (5-reaction system)

¹Tu, C.-P.D. and Cohen, S.N., Gene, 10: 177, 1980

5' End Labeling

Adapted from procedures described by Maxam and Gilbert, an efficient, time-saving means of labeling nucleic acid fragments preparatory to DNA sequencing (see next column). The system includes ATP, $[\gamma^{-32}P]$ - with polynucleotide kinase prepared in our own laboratories, and a carefully balanced complement of buffers, enzymes, and other reagents necessary for labeling the 5' termini of DNA fragments.

Systems sufficient for either 10 or 5 reactions contain the following:

ATP. [v-32P]-

Alkaline Phosphatase

Polynucleotide Kinase (purified to

homogeneity)

Phosphatase Buffer

Direct Phosphorylation Buffer Exchange Phosphorylation Buffer Hinf I Digest of Plasmid DNA,

pBR322 (control to check system) Deionized Water

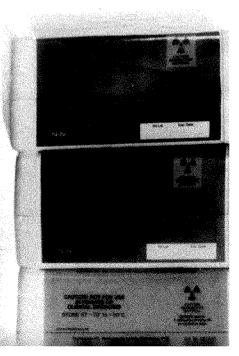

The system is tested the day before shipment using the same lots of components you will receive, including fresh tracer. The resulting

autoradiogram is included with your system.

Ordering information:

NEK-006 (10-reaction system) NEK-006A (5 reaction system)

NEW DNA Sequencing

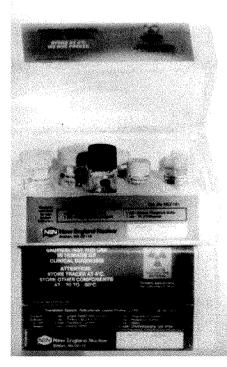

his system follows the Maxamilbert procedure as published in lethods in Enzymology and ncludes the entire text of the artile. It is suitable for sequencing NA labeled with our 3' or 5' End abeling Systems and includes all eagents necessary for the four ase specific cleavage reactions. ufficient material is provided for at east fifty of each reaction.

he following components are icluded:
Dimethyl Sulfate
Hydrazine
Piperidine
Piperidine Formate
Ferric Chloride
Sodium Hydroxide
Maxam-Gilbert Procedure Manual

ach new lot of components is ested before shipment in a seuence analysis of a DNA fragment. The purity of each component is nonitored using chromatographic nalysis and documented for aclusion with the system.

Ordering information: NEK-010

faxam, A.M. and Gilbert, W., Methods in nzymology, 65 (1980)

NEW

Transcription

This system provides all the components necessary to perform eukaryotic cell-free transcription. It contains a cell-free extract derived from HeLa cells which catalyzes the synthesis of mRNA precursors when provided with an exogenous DNA containing a promoter for recognition by the polymerase. This RNA polymerase II dependent reaction is highly sensitive to the presence of α -amanitin. The whole cell extract is prepared as described by Manley and coworkers.³

The system also includes UTP, $[\alpha^{-32}P]$ - for labeling specific mRNA precursors. A control DNA template, the cloned Bal I-E restriction fragment of Adenovirus-2, has been used to optimize the system and is included with it. This control should be used by the investigator to determine proper functioning of the system.

Components sufficient for performing 50 assays (25μ l reaction volume) are listed below:

UTP, $[\alpha^{-32}P]$ HeLa Cell Extract
Control DNA Template
Transcription Cocktail
Deionized Water

Ordering information: NEK-014 (50-reaction system)

³Manley, J.L., Fire, A., Cano, A., Sharp, P.A., and Gefter, M.L., *PNAS* (U.S.A.), **77:** 3855 (1980)

Translation

Now Proline [3H]

NEN's *in vitro* protein translation systems have made cell-free translations of eukaryotic mRNAs exceptionally reliable and reproducible. These systems are offered with either Methionine, L-[35]- or Leucine, L-[3H]- or Proline, L-[3H]- labeled tracers. All three utilize an extract of rabbit reticulocyte lysate that has been treated with micrococcal nuclease to remove endogenous mRNA. The lysate is prepared under strictly controlled conditions to ensure retention of high protein synthesis activity.

The components include:
Rabbit Reticulocyte Lysate
Methionine, L-[35S]-, or
Leucine, L-[3,4,5-3H]-, or
Proline, L-[2,3,4,5-3H]Translation Cocktail
Control mRNA
Magnesium Acetate
Potassium Acetate
Deionized Water

Each lot of systems is biologically tested with the control mRNA. A graph demonstrating Methionine, Leucine, or Proline incorporation is provided with your shipment.

Ordering information:

Go with Eupergit!

The NEW carrier for immobilization of biomolecules for biocatalysis and affinity chromatography.

- electroneutral, hydrophilic matrix with electroneutal, covalent binding mechanism
- high binding capacity due to high epoxide group content
- macroporous structure with a low water uptake
- high mechanical stability for large-scale industrial processes. Excellent flow properties and good filtration and centrifugation characteristics
- high chemical stability of the matrix and of the bonded ligands
- water uptake independent of pH and ionic strength (from pH 0-14).
- capability of reacting with low-molecular weight ligands in water or in organic solvents

Eupergif - your real choice!

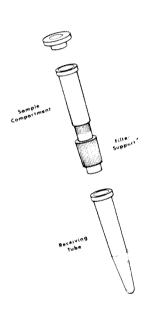

Röhm Pharma

Postfach 4347 D-6100 Darmstadt 1 West-Germany Please send more detailed informations about EUPERGIT to

Centrifugal **Microfilters**

Bioanalytical Systems introduces a centrifugal microfilter for membrane filtration of small volumes using the force of a conventional bench top centrifuge. Ideal for LC sample preparation, extraction of TLC spots, and many other applications.

- minimize loss and contamination
- no vacuum or pressure required
- solvent resistant polyalo-
- filter many samples simultaneously
- a variety of filter materials are available
- reusable

text books from **MACMILLAN**

FROM DNA TO PROTEIN: The Transfer of Genetic Information MARIA SZEKELY

This is the first textbook which discusses gene structure on the basis of recent discoveries of overlapping and split genes and which genetic information can be encoded into the genetic material and how it can be transferred to other materials.

A perfectly up-to-date account of our present knowledge of the structure and expression of genes in prokaryotic and eukaryotic organisms and the only available text showing the correlation between the structure and function of nucleic acids.

HUMAN REPRODUCTION AND DEVELOPMENTAL BIOLOGY

D. J. BEGLEY, J. A. FIRTH and J. R. S. HOULT

An integrated approach to describe the cellular and physiological processes of human reproduction and embryological development in relation to their underlying mechanisms and to their practical applications in medicine. The book combines anatomy, biochemistry, physiology and pharmacology, making it more suitable for modern preclinical and human biology courses. February, £20.00, 0 333 23423 5

£9.95, 0 333 23424 3

GYNAECOLOGICAL CYTOLOGY

MATHILDE E. BOON and METTE LISE TABBERS-**BOUMEESTER**

Dr Boon and Dr Tabbers-Boumeester have, over the past ten years, developed the course in diagnostic cytology which was first given in Leiden in 1969.

In this volume they present their insight into both the study of diagnostic cytology, and into the teaching of this increasingly important subject. To illustrate the modern concepts of cytopathology, examples of more advanced approaches are included: as well as scanning and electron microscopy there are details of DNA measurements, morphometry and immunopathology.

20 August 1981

Saving antibiotics from themselves

For how much longer will antibiotics remain at the disposal of physicians? This is the question that will be raised in the public mind by the gloomy statement put out earlier this month from Boston by a group of participants in the conference on the Molecular Biology, Pathogenicity and Ecology of Bacterial Plasmids held in Santo Domingo last January. The statement, in which Professor Stuart B. Levy of Tufts University has played a prominent part, points to the spread of resistance to antibiotics among bacteria in recent years, says that the "worldwide public health problem" is "due in large part to the indiscriminate use of antibiotics" and goes on to urge that "national and international committees" should be set up so as to issue "directives for prudent antibiotic use". Dr Levy's group is anxious that attention should widely be paid to its clarion call.

Nobody dissents. The problem of antibiotic resistance, although something of a surprise because thirty years ago nobody anticipated the versatility of bacterial plasmids, is, nevertheless, not new. Good sense argues in the same direction as Dr Levy's group: plainly everybody - not merely physicians but public health officials and farmers - should be more discriminating in the use which they make of a class of compounds, for the time being invaluable, whose value is being eroded as the years go by. Less vitally (in the human sense), the same process has been happening with insecticides, the other principal biochemical legacy of the 1940s. Organisms of all kinds, not only bacteria but insects as well, constantly surprise us by their biochemical versatility. (So, too, do higher organisms such as human beings, which have demonstrated a remarkable capacity for survival in circumstances in which self-adulteration with materials such as alcohol is common, although there is no reason to suppose that selection has played any significant part in this process.) How do we learn to live with such surprises?

The question is every bit as important as the statement earlier this month makes out. It is more than merely wasteful, but tragic as well, that the benefits of technological innovations (antibiotics, insecticides) should irreversibly be misused. Superficially, these sombre prospects are more galling than the waste of the potential benefits of mechanical technology — air transport (hamstrung by protective regulation), telecommunications (often hamstrung by protective legislation) and computer technology (hamstrung by collective inertia). For there, the argument goes, the promise remains, waiting merely on some kind of reform of people's resolve to make sensible use of the tools that science and technology have provided for them. But is it not also tragic that in present circumstances the productive wealth of the industrialized nations should be constrained, with all the human consequences that are entailed — and measured by the growing proportions of the unemployed — and that the gap between the prosperity of the rich and the poor should, through mutual impoverishment, be sharpened? Society, in other words, is as much at risk from the under-use as from the over-use of the technology at its disposal.

How, against this background, should enlightened policies on antibiotics be designed? Dr Stuart Levy's group, recognizing that policies of some kind need to be devised, has been plainly at a loss to know how these might come into being. Why else would it have suggested a hierarchy of national and international committees? This strategem, the most obvious, is well calculated to amplify its own eloquent statement of foreboding about the consequences of the misuse of antibiotics, but unlikely to make much headway with dealing with the causes of misuse. These, in turn, are deeply embedded in the ways of societies blessed with the chance of using

antibiotics — the freedom of physicians to prescribe, the freedom of other professional people (farmers, for example) to use chemical products in ways that they think proper and profitable and the general restraint on democratic government from excessive interference with what people do (or do not do). Dr Levy's group, for all the best reasons, finds itself up against the kind of social ethos that made the discovery of antibiotics possible. That, it may be thought, is the irony of their (and our) dilemma. How is it to be resolved?

The dismal science would suggest a simple remedy, not entirely to be scorned. If some uses of a potential social benefit are judged democratically to be prejudicial for society at large, why not put a tax on them? The snag is that the demand for antibiotics is greatest in those societies in which the prices of supposedly lifesaving drugs have the least negative effect on the demand for them; elsewhere, where the "need" is perhaps greatest, the "demand" (muted by the capacity to pay or even by ignorance) is least. An alternative solution may be found in the common ethics of the medical profession, which increasingly requires that physicians should balance the benefit that a single patient will receive from a certain treatment against the more general benefit if the resource in question is dispensed in some other way — the allocation of a kidney machine to one person rather than another, for example. In the use of antibiotics, the counterpoise of individual benefit is, however, non-use for the greater good. Logically, the problem is the inverse of that in which physicians subject their patients to the small risk of damage from the use of a vaccine (coupled with the benefit of immunity against the corresponding infection) for the sake of the wider benefit. The trouble is that non-use is certain to be regarded, in democratic societies, as deliberate and thus reprehensible neglect. How, in the last resort — as it may be — does a physician explain that the administration of an antibiotic likely to be beneficial must be withheld for fear that resistance will be encouraged?

Physicians properly concerned about problems of antibiotic resistance must manage more adequately to come to terms with the societies in which they work. It would, of course, in many other fields than this, be splendidly simple if individuals would put their expectation of personal benefit second to the communal benefit, even in matters of life or death. In the short run, however, that is exceedingly unlikely. And there is no immediate prospect that there will quickly arise such a persuasive analyst of the machinery of society that some compromise will be found between the doctrines of the two greatest analysts so far - Adam Smith (who can be bowdlerized as holding that the communal good is the sum of individuals' estimates of their individual benefit) and Karl Marx (whose essential argument, grossly oversimplified, is that the greater good will benefit most but not all individuals). So what should physicians do about antibiotics? The hierarchy of committees now proposed, potentially useful, should be given positive rather than negative terms of reference. The objective should be somehow to suggest things to do rather than not to do - handlists for physicians to help them to make empirical decisions, programmes for the more effective control of infection in hospitals, plans for helping forward the development of new kinds of antibiotics (for research people are even more adaptable than bacteria) and, above all, studies of how a proper balance between use and non-use is to be struck in modern democratic society. Nobody will pretend that these tasks are simple. In the long run, however, nobody will listen seriously to Dr Levy's group unless it tackles these broader subjects.

London bites private bullet publicly

University cuts spending across the board

The University of London last week let its constituent colleges know how much they will have to spend next year, and how many students they will be permitted to educate three years from now, in 1983-84. The target reductions of the student population are in line with the gloomier forecasts; most colleges are disappointed with their financial allocation for the academic year immediately ahead.

Some, however, are relieved. Earlier this year, Chelsea College, one of the science-based smaller colleges in the university, was singled out by the second interim report of the Committee on Academic Organization commissioned by the university for oblivion or dismemberment; Chelsea is therefore understandably relieved that the now threatened reduction of its student numbers three years hence is a mere 14 per cent.

Other colleges, previously thought to be set fair, have been downcast. Queen Elizabeth College, for example, applauded in the most recent interium report of the Committee on Academic Organization (under Sir Peter Swinnerton-Dyer) has been asked to plan for a student body reduced by a third three years from now. The reduction is even more drastic than that decred by the University Grants Committee for the University of Aston in Birmingham.

Under the university's plan for the cutting of the cake for the coming academic year, the larger colleges do best. University College London, singled out for its high unit costs, by the Swinnerton-Dyer Committee, will have to stomach only a five per cent cut in student numbers in the next five years.

In its letter to schools of the university last week, the Court said that it had decided to take full account of the recently decreed increase of fees for part-time students, but had made a special but interim provision for Birkbeck College (most of whose students are part-time). On overseas students (or the lack thereof) the Court said that it could not undertake to help those branches of the university hard-hit by recent changes.

The Court's letter contains an element of second guessing in the statement that it has "devised arithmetical values for the various UGC verbal indications about Arts and Sciences". The upshot of the Court's calculation seems to be that, after allowing for the buoyant future spelled out for Imperial College, the population of science

students in the rest of the university will decrease by 11.3 per cent in the next three years, compared with the reduction of 5.7 per cent expected in other academic fields.

The university court seems, nevertheless, to have been perplexed by some of the consequences of its arithmetic. Given the substantial reduction of student numbers in science foreseen, and the grants committee's recommendation (to the university as a whole) that special attention should be given to veterinary science, mathematics and engineering, the Court records that it enquired whether a reduction was required in biology.

Apparently it "emerged" that the committee had not intended that the

subject group of "biological sciences" should "suffer such a large reduction" but that the committee was in favour of a reduction of the numbers of students following degree courses combining two science subjects, "a category not specifically mentioned in the UGC letters".

On balance, the Court has planned for a real reduction of 5 per cent in its resources in the coming academic year. Given previous commitments to medical and other professional schools in the university, the Court says that the generality of its dependants will have to make do with 7.5 per cent less in the coming academic year.

Soviet Union urges space demilitarization

The Soviet Union has proposed a new treaty banning the deployment of weapons in outer space. The terms of the treaty, set out in a letter from the Soviet Foreign Minister, Andrei Gromyko, to the Secretary General of the United Nations, Dr Kurt Waldheim, differs from the 1967 treaty on outer space in two important respects. It covers all weapons, and is envisaged as an instrument of the United Nations, to be available for signature by "all states" with the instruments of ratification deposited with the United Nations Secretary General and not, as in 1967 with individual sponsoring governments. Accordingly, in the opening clauses of the draft, the text, refers to 'member states'' and switches to "signatories" only in details dealing with the technicalities of ratification, amendment and possible withdrawal. According to TASS, the essential articles of the draft read as follows:

- 1.1 The member states undertake not to put into orbit around the Earth objects bearing weapons of any kind, not to install such weapons on celestial bodies, and not to deploy any weapons in outer space in any other way including on piloted spacecraft of multiple use both of the existing type and also of other types which may be developed in the future by member states.
- 1.2 Each member state... undertakes not to help, encourage and incite any state, group of states or international organization to engage in activities running counter to the provisions of paragraph 1 of the present article.
- 2. The member states shall use spacecraft in strict accordance with international law including the UN Charter in the interests of maintaining international peace and security, and for the development of international cooperation and mutual understanding.
- 3. Each member state shall be bound not to destroy, damage or disturb the normal functioning or alter the flight trajectory of space vehicles of other signatories.
- 4. For the purpose of ensuring confidence in the observation of the provisions of the present treaty, each member state shall use

the national technical monitoring facilities at its disposal in such a way as to comply with the generally accepted principles of international law.

The document is, of course, only a draft, and with the United States toying with orbital laser weapons seems unlikely to achieve anything concrete in the near future. The US shuttle, however, and its possible military implications have been causing considerable concern to Soviet military experts. The past few months have seen numerous comparisons in the Soviet media between the "militarist" capabilities of the shuttle and the essentially peaceable nature of the Soviet Salvut orbital stations. Such concern seems, at least in part, to lie behind Mr Gromyko's letter to Dr Waldheim, which notes that the risk of the militarization of outer space has "recently

If the treaty should materialize, several ambiguities in Mr Gromyko's draft would doubtless have to be resolved. Thus article 3, as it stands, seems to leave open two justifications for damaging or disturbing a spacecraft in flight — that it was not (or was erroneously thought not to be) the property of a member state, or that it was allegedly launched in breach of article 1.1. Again, the draft contains no clear definition of a 'weapon''. In its strictest sense, article 1.1 would preclude even the carrying of a hand gun or life-preserver by, say, senior officers of a large space station. Such a station, too, might well wish to deploy small rockets with explosive warheads to destroy artificial debris or meteors on a dangerous approach course. Would such rockets be classed as "weapons" if they were "accidentally" launched against the spacecraft of another signatory? Moreover, just as in 1967, the treaty makes no provision for inspection, simply calling (article 4.3) for consultations and exchange of information "where necessary". Without such provisions, any such treaty would be little more than an Vera Rich ethical gesture.

UK biotechnology

Fast start

Britain's "official" biotechnology company, Celltech Limited, seems not yet to have decided how to respond to Stanford University's advertisement of terms for non-exclusive licences to exploit the Boyer-Cohen patent. Part of the difficulty is that it is not yet clear how far companies outside the United States, part of whose business will come from the licensing of their own patent rights to other non-American companies, will be affected by the patent. But there is also an element of waiting and seeing. So far there have been no direct talks with Stanford.

In any case, the company is probably too busy. Since Celltech moved into its new headquarters in Slough (20 miles west of London) just after Christmas, the staff has grown more quickly than originally foreseen, to just about sixty. The company seems pleased with the eagerness of scientists to join up, mostly from industrial companies but with a substantial proportion of people from the universities.

One of the newest and most significant recruits is, however, a sales invoice clerk. Although the company's prospectus has made no bones about the time that will be needed to put biotechnology on the commercial map, it does plan to sell what it can as soon as it can. One of the first products will be an anti-interferon monoclonal antibody, principally for use by the manufacturers of interferon. A laboratory for the preparation of this and other monoclonal antibodies is being assembled. But the company is anxious that this part of its business should not be thought of as more than a kind of sideline.

Understandably, the company is reluctant to say where its chief efforts will go, but gives the impression that it will not be investing a major effort in the production of interferon of any kind. At some stage, though, it seems clear that Celltech will be in the industrial enzyme business. For the time being, the practical aim seems to be to establish itself well in the basic techniques of genetic manipulation, among which nucleic acid chemistry and the techniques of gene expression are conspicuous.

The nucleic acid chemists have built themselves an automatic nucleotide assembly machine rather than buying one off the peg, chiefly for the flexibility that results. They claim that their machine will add nucleotides (up to a score or so) at the rate of one every half an hour, which means the production of one full-length oligonucleotide during each overnight run.

Celltech's fast start means that its initial capital of £12 million will be used up more quickly than originally foreseen. The plan now is to recruit up to 150 people by September 1983, half of them scientists.

The shareholders in the company (among whom the National Enterprise

Board is the largest, with 44 per cent) have agreed to the accelerated investment plan, and will take a close look at its successor in just over two years time. The officers of the company say that they are heartened by the long-term view taken by the shareholders, which also include the Prudential Assurance Company, the Midland Bank, British and Commonwealth Shipping and Technical Development Capital. This, the guess is, should give Celltech a good chance when, in two or three years, there is likely to be a shakeout in the biotechnology field.

The company has no fixed ideas about the way in which it will sell its products, but plans not to enter the marketing of manufactured products nor manufacturing as such (which does not exclude the setting up of manufacturing companies in partnership with others). Enquiries from industry have been flowing in, some of which may lead to research contracts.

On the relationship between Celltech and the Medical Research Council, on whose developments the company has first refusal, Celltech says that developments not of direct interest may be licensed to others, in which respect the company will act as a kind of broker. It expects, however, to make direct use of most of the ideas suggested by the Medical Research Council, which, nevertheless, retains the right to bypass Celltech if too much time passes.

US graduate salaries

Engineers ahead

Washington

Statistics for 1980 recently released by the US Department of Education show a significant increase in the number of bachelors and first professional degrees in science and engineering awarded by US colleges and universities for the first time since the early 1970s.

The main reason for the increase is a growth of 11.5 per cent in the number of engineering graduates, continuing a trend that started in 1976. Since then, the rise has been balanced by a drop of about 4 per cent a year in the number of graduates in the social sciences and psychology — there was a drop of only 1.2 per cent in 1980.

The continued growth in engineering graduates reflects the relatively high salaries that even first-degree graduates are being offered by industry. Figures published by the College Placement

Council two weeks ago showed that 1981 graduates are entering jobs with starting salaries between 10 and 14 per cent higher than a year ago.

The average starting salary for petroleum engineers with a bachelor's level degree was \$26,652, and for chemical engineers \$24,360. This compares with starting salaries for economists with similar qualifications of \$16,440, and for other social scientists of \$13,992.

The high salaries being offered by industry also seem to be discouraging engineering graduates from staying on to complete higher degrees, leading to difficulties in higher education institutions of attracting qualified teaching and research staff. In comparison with the 11.5 per cent increase in bachelors' and first degrees awarded in engineering, the number of masters degrees in the same subjects rose by only 4.3 per cent, and the number of doctors' degrees remained virtually constant.

Concern about the implications of these figures has prompted Congress to oppose President Reagan's plans to eliminate the National Science Foundation's support for graduate fellowships. Committees in both the House and the Senate have agreed to restore funds for the fellowship programme, which makes about 500 new awards a year, although the precise level of funding for the foundation's overall education efforts has still to be negotiated between the two legislative bodies.

Another problem now emerging is a shortage of qualified science teachers. States have experienced a rapid decline in the number of science teachers turned out by their colleges of education; in physics, for example, the supply of new secondary school teachers has virtually dried up at a time when warnings are being voiced in Washington about the dangers of a growing "scientific illiteracy" among the general population.

According to Dr James Rutherford, who has been appointed director of a new science education programme within the American Association for the Advancement of Science, many schools are reporting that their science teachers are being approached with tempting job offers from private companies — often mathematics and physics teachers are offered jobs in computer sciences at salaries considerably higher than they receive for teaching.

David Dickson

Degrees awarded in 1980 (figures from National Centre for Education Statistics)

	Bachelors' professiona		Master	s' degrees	Doctors' degrees		
Total	1,009,879	(+0.9%)	299,492	(-0.9%)	32,758	()	
Science and engineering	292,271	(+1.2%)	54.463	()	16,495 (+ 0.8%)	
Science and mathematics	117,906	(-1.1%)	,	(-1.2%)		+1.0%)	
Social sciences and psychology	114,469	(-1.2%)	15,552	(-2.7%)		+0.8%)	
Engineering	59,903 (+11.5%)		(+4.3%)		+0.1%)	

Values in parentheses are per cent changes from 1979 figures; a dash indicates no change.

Indian health care

Keeping it simple

Lucknow

If India's ambitious target of "health for all" by the year 2000 is to be approached, then the present curative hospital-based, urban-centred health service may have to give way to simpler low-cost alternatives, especially in rural areas.

Some advances have been made in developing "appropriate technology" for health care. Low-cost audiovisual aids and teaching methods for various levels of health worker have been developed under the aegis of the Indian Council of Medical Research. The Central Scientific Instruments Organization has developed a cycle-ambulance with a stretcher for the patient and a seat for the attendant; a clinical thermometer with temperature ranges indicated as coloured bands for easy use by illiterate health volunteers; a simple apparatus for vasectomy, now ready for human trial; a fetal stethoscope which can detect a fetal heart beat at week 12 of pregnancy; a miniature cardioscope and a colorimeter. The Vector Control Centre, Pondicherry, has demonstrated that certain fishes such as Aplocheilus blochii and Gambusia affinis, can be used as effective controls of mosquitoes, on whose larvae they feed.

For maternal and child health care by traditional birth attendants, called dai, a simple dai kit has been developed at the Postgraduate Institute of Medical Education and Research, Chandigarh. The kit should reduce the risks of tetanus, by achieving better asepsis, and helps the birth attendants to spot mothers and infants at risk—again using colour-coding principles on measuring sticks and weighing scales.

A much-needed boost to rural health care should come with the recent decision of the Indian government to set up a national committee on appropriate technology for health care. The Indian Council of Medical Research is to provide technical support for the national health programme—and at a national workshop held recently by the council the value of community health volunteers and multipurpose health workers was underlined.

Zaka Imam

Blood products

Surplus sale

Products extracted from donations to the British National Blood Transfusion Service, and for which the National Health Service has no use, may in future be sold to pharmaceutical companies, the government has decided. Although some companies have occasionally bought products from the transfusion service in small quantities, usually for research purposes, there have been no formal arrangements for buying in bulk. Thus British companies have had to buy from abroad.

The decision to sell off surplus blood products has emerged from a lengthy wrangle over the use of products that are now discarded, expected to be exacerbated as the transfusion service puts into operation a plan to make more blood plasma available for fractionation. There has also been a long discussion about the revamping and expansion of the Blood Products Laboratory, which carries out all fractionation of donated blood. The laboratory suffers from some of the problems of the former Lister Institute of Preventive Medicine, whose site it shares. The institute was closed in 1978 after it began to lose money and could not afford to modernize its facilities.

An earlier government suggestion that the Blood Products Laboratory be handed over to commercial management fell flat after many organizations, including blood donor groups, trades unions and Labour Members of Parliament, objected to the rise of blood donated by volunteers for overtly commercial purposes. As a compromise, the government has decided to keep the laboratory firmly under the wing of the Department of Health and to sell products surplus to the National Health Service's requirements. Any profits will be ploughed back into the health service, although it is not yet clear whether they will be spent on updating the laboratory.

The success of the scheme will depend on whether the laboratory can supply companies with products they need. Companies are negotiating with the health department, which has said only that outdated red cells and plasma fractions containing nonspecific antibodies will be available. Products for which the health service's demand exceeds supply, however, will not be for sale. They include factor 8, the blood clotting agent used for treating haemophiliacs, and albumin.

Future sales will, however, depend on the plan to make more blood plasma available for fractionation, by substituting concentrates of red cells for whole blood in transfusions and on the laboratory's ability to take on the extra work. The aim is that by the end of 1982, the laboratory will have enough plasma to produce two-fifths, compared with one-fifth at present, of the national demand for factor 8, in which it is hoped that Britain will ultimately be self-sufficient. That will mean that other products, such as factor 9, immunoglobulin and albumin, will be produced in excess and will be available for sale.

One company now discussing its needs with the Department of Health is Beechams Pharmaceuticals Limited, which would like to buy plasminogen for clinical trials in the treatment of deep-vein thrombosis. Whether the laboratory will be able and willing to supply such specific products, or will simply make certain plasma fractions available, remains to be seen.

Judy Redfearn

Paying court

Forensic scientists in Britain are rather touchy at the moment, following the suspension of one of their number for allegedly failing to reveal crucial ambiguities in evidence on blood samples, and now the "demotion" of another for writing a research paper which is said to reveal detachment.

This second scientist resigned rather than accept a teaching post — which he regarded as demotion — and then went to an industrial tribunal to claim what he saw to be effectively unfair dismissal. However, the tribunal rejected the scientist's claim, and he is to appeal to the Employment Appeal Tribunal in London on 3 September.

His paper, which appeared in the official journal of the British Academy of Forensic Science - Medicine, Science and the Law — in 1977 (vol. 17 no. 1, p.37), deals with the quantitative toxicology of corpses — addressing the issue of how to estimate a drug or poison dose. The paper uses a simple law of linear diffusion to relate the drug content of various organs (taken from the data sheets of real cases) to dose and time of death as estimated by the police and witnesses. The data are clearly very scattered and the fit loose, and the author concludes "A pessimistic view is that it is impossible to remove the last vestiges of alchemy from [forensic] toxicology because of the nature of the material for analysis. It may be, apart from the fact of death, that one cannot be absolutely certain of anything and there are always contrary authorities to be found".

This conclusion may not have recommended itself to the Forensic Science Service, which as part of the Home Office runs forensic science in the United Kingdom. Other forensic scientists may equally have been unsettled.

Robert Walgate

US uranium

Falling demand

Washington

A report from the US Department of Energy (DoE) has revealed just how depressed the domestic market for uranium has become. This was already evident from the dramatic price reduction in 1980, when uranium oxide fell from \$43 to less than \$30 a pound. Now DoE has shown that, for the first time, the amount of new orders for future supplies placed by US utilities was more than outweighted by cancellations of existing commitments.

The DoE's report, A Survey of United States Uranium Marketing Activity, published last week, is based on information gathered from 60 utilities with nuclear reactor projects, 30 present or potential uranium users and five reactor manufacturers. It says that domestic

buyers contracted with US primary producers for an extra 12,500 tons of $\rm U_3O_8$ in 1980, but that this was offset by a reduction of 25,600 tons for commitments made under previous contracts.

The survey showed that, despite the current depressed prices, most utilities and producers expect the price of uranium to rise sharply over the next decade; future contracts which guarantee a floor price for any 1 year quote an average of \$75 a pound by 1990.

The drop in uranium demand is blamed on the extended licensing period faced by companies building new reactors, a reflection of increasingly stringent safety requirements and on the substantial reduction, in estimates for future demand for electricity as the United States becomes more conservation-conscious, and energy costs continue to rise.

Some business analysts feel that the price of uranium may have bottomed out, at least temporarily. According to calculations by the Californian consulting company Nuclear Exchange Corporation (Nuexco), uranium prices remained virtually constant at \$24 a pound between April and June, and actually increased slightly last month.

However, the slump in prices — and demand — is clearly reflected in difficulties being faced by the uranium mining industry. Some estimate that as many as 4,000 workers, 25 per cent of the workforce, have been laid off.

This decline, too, is reflected in DoE statistics. In another report, soon to be published, the department notes that the uranium mining industry is entering a period of major retrenchment. Having initially planned to spend \$316.5 million on new mining facilities in 1981, for example, the industry now estimates that total spending will be only about \$172 million. Projections for capital spending on mill facilities have dropped even more dramatically, from \$241.9 million to \$99.3 million.

According to DoE officials, several processes are keeping the price of uranium oxide down. One is that many utilities, faced with high interest rates, are selling stockpiled uranium back to producers. Another is that, even though uranium mining has been cut back, production figures are still going up as companies work through stockpiles of ore. Nuexco had predicted a drop of 2.5 million pounds between 1979 and 1980 to about 34.5 million pounds — still about double the amount consumed by the nuclear industry.

In fact, however, production increased by 13 per cent to 42.5 million pounds. Some wastes which have already passed through the mill are being rerun, a way of obtaining more uranium oxide without having to pay for any extra mining. Some industry analysts feel that this will continue, so that even if demand picks up it will not be reflected by an immediate boost for the mining industry.

David Dickson

German cancer research

Politics ousts science

Brussels

The scandal at the German Cancer Research Institute has grown into a national issue. The scientific director has resigned, the administrative director appears to have been removed, the oppositions parties (CDU/CSU) have attacked the government and the institute itself is now involved in internecine strife.

The national research centre in Heidelberg is a union of eight institutions centrally administered by the Bundes Ministerium für Forschung und Technologie (BMFT), with a 1981 budget of DM 79 million (\$1,817 million). The latest scandal began with the appointment of Dr Hans Neurath, born in Vienna, but previously professor of biochemistry at the University of Washington, as the centre's scientific director. The post had been vacant since 1976 and the chief administrator, Bodo Spiekermann, was relieved to have found someone with the qualifications and drive to attempt the much needed reorganization.

The other directors of the centre were not consulted about the appointment and soon raised a storm about the professor's demand that the institute pay for a villa in addition to his salary of DM 167,000 a year. The attack soon broadened to Neurath's qualifications and it turned out that he had in fact previously only been scientific advisor to the University of Seattle.

The centre's director for toxicology and chemotherapy, Professor Dietrich Schmaehl, declared that Neurath could not possibly be sufficiently knowledgeable about cancer research to take over leadership of the centre. Nothing daunted, Neurath set about appointing outside investigators to assess the value of the research projects in hand with the intention of directing resources to the most promising areas. The multidisciplinary, clinically-orientated approach was rejected, and Neurath, with the support of the ministry's director, Wolfgang Spinke, proposed to cut back on activities such as nuclear medicine and chemotherapy.

The zeal with which Neurath set about reforming the institute inflamed the already poisoned atmosphere, the battle amongst the divided researchers spilled over into the press and by May this year it had become a political issue, with the opposition, CDU/CSU, siding with Neurath's opponents and the government defending its appointee who by then had been in charge for a year.

The opposition claimed that the administration of the centre was chaotic and scandalous. By July CDU/CSU was describing the working climate as completely destroyed by internal power struggies complete with the "terrorization of administrative personnel".

On 24 July, Neurath announced that he

had resigned but would explain the reasons for his decision only in September. BMFT also announced that Spiekermann was being withdrawn, and the conflict became an out and out battle between the ministry and the research centre. The ministry now plans to examine the scientific activities of the centre since 1973.

The latest chapter in the saga is the government's reply to the CDU/CSU's accusations in July. It reaffirms BMFT's desire to strengthen pure research rather than to concentrate on already well-explored areas. In addition, the government says it has long been convinced that the quality of the centre's research could be improved and that the routine work carried out runs counter to the aims of the centre. "Internal egoism", it says, has been responsible for the present situation; the attack against Neurath is merely an attempt to divert discussions from the real issues at stake.

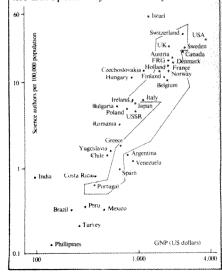

Jasper Becker

Productivity by numbers

India, Eastern Europe and Israel stand out as being unusually scientific in the accompanying graph prepared by sociologist Dr Pedro Gonzalez-Blasco of the University Alcalá de Henares, Madrid.

The plot shows the number of scientists per hundred thousand population against gross national product (GNP) per capita in 1967. The box encloses Western European countries. The main trend is for the proportion of scientists to rise at about the third power of GNP per capita — so that scientists are added more rapidly per unit of additional GNP the higher the GNP. However, this may be read in two ways. Are the countries above the trend more effective at creating scientists? Or are their scientists less effective at creating wealth?

Dr Gonzalez-Blasco's plot forms part of the background to a seminar on the state of physics in certain less developed European countries to be held in Istanbul on 4-5 September under the auspices of the European Physical Society.

CORRESPONI

Badger vaccination

Sir — It was noble of Mr Rees (Nature 9 July, p.104) to come to the defence of the Zuckerman report; however, my criticisms were of the report rather than the Ministry.

Mr Rees misreads my plea that some attention should be paid to vaccination of badgers, as advocacy of vaccination as the answer.

It is well known that BCG is one of the less effective vaccines in man, both in the percentage of the population protected, and in the type of protection afforded (infection is not prevented, it is merely limited). Reports have shown that protection can vary from 78% of the vaccinated (human) population at best to negligible responses at worst. However, protection of only some of the population is epidemiologically significant, and whilst protection may not be absolute it is of proven value in reducing the transmission to further individuals - the significant factor here. The epidemiological basis in controlling a disease is to reduce the number of individuals infected by each diseased animal in its lifetime to less than one. Therefore any means of reducing the number of susceptible individuals contacted by each infected badger will be of significance. (Gassing undoubtedly comes into this category).

Though attempts to vaccinate foxes orally (against rabies) have shown what problems there can be, badgers are well known among zoologists for the ease with which they will take quite considerable quantities of easily prepared oral baits. This has been used to advantage in a variety of ecological studies.

The degree of infection in some areas was also cited as a reason against vaccination, and whilst gassing may be the most effective approach in severely affected areas, it is nevertheless still the case that vaccination alone, if feasible, would have some positive effect. What does not appear to have been considered was the value of vaccination in less infected areas, or even ring-vaccination around those areas to be gassed (migration into cleared areas being a problem).

At this stage all conjecture is limited by the lack of knowledge. However, I must still regret that the report did not more positively specify research aims. I still believe vaccination to be one of these.

M.J. CHAPMAN

Easingwold, York, UK

White or brown?

Sir - Concluding his review of two important books of contemporary scientific and medical interest on dietary fibre and health1, John Yudkin says "Let us by all means eat brown or wholemeal bread if we like it. But let us not delude ourselves that it will make us healthier or prolong our lives". This statement is not justified by the data available on the efficacy of dietary fibre in lowering disease risk. There may be useful effects of certain dietary fibres in preventing or ameliorating intestinal

diseases in general, but this aspect is for others more expert to discuss^{2,3}. We now comment on the scientific aspects of fibre use in relation

Countries with a high incidence of atherosclerosis and coronary heart disease usually have a high incidence of colon cancer, and vice versa⁴⁻⁶. For example, Great Britain has a high incidence of both kinds of disease, the Japanese a low incidence. Finland is an exceptional country, exhibiting a high incidence, in fact among the highest in the world, of atherosclerosis and myocardial infarction; however, interestingly, their colon cancer incidence is only slightly higher than that of Japan, but much lower than the other Scandinavian countries^{7,8}. Independent groups in the United States and Europe have investigated the underlying mechanism^{9,10} Detailed inquiry showed that the Finnish people consumed a diet not too different with regard to the amounts of most components, especially lipids and proteins, from those of people in New York or Copenhagen, so, by current concepts their diet and nutrition account for their high incidence of heart disease. However, the Finnish people also consumed rather large amounts of whole grain bread and other sources of cereal fibre. resulting in a stool bulk two to three times larger than those of the populations in New York or Copenhagen. At the level of metabolic epidemiology^{9,10} specifically in relation to secondary bile acids which were demonstrated to be promoters in the carcinogenic process11, the people in Finland and New York showed the same total bile acid levels, as would be expected with similar lipid intakes. However, and importantly, because of the increased stool bulk in Finland, the concentrations of bile acids were much lower similar to the concentration found in Japan. The Japanese level was that low, not because of high fibre intake, but because of low fat intake¹². Thus, the epidemiology was explained by metabolic biochemical approaches, and it was demonstrated through studies in man that cereal fibre accounted for a decreased risk of colon cancer in Finland. Furthermore, parallel studies showed that cereal fibres, particularly bran, could decrease the incidence of colon cancer in animal models^{13,14}. The few instances where this was not so involved feeding the fibre during the period when carcinogen was administered, but not during the important promotion phase 15, or when too high a level of carcinogen was administered, thus overwhelming the promotion phase where cereal fibre exerts its major protective role16.

To be sure, more research is necessary on the effect of diverse fibres, and in fact on the effect of other micronutrients. Unlike Yudkin, we believe that the present data base is adequate to conclude that brown or wholemeal bread with adequate fibre and other whole grain cereals, such as bran-containing breakfast cereals, are not only tasty but, indeed, have every chance of reducing the risk of colon cancer, a major type of cancer in the Western world. It is so easy to implement, and in fact would simply be a return to the situation prevailing before extensive milling of cereals removed much of the valuable fibre. Thus, adverse health effects owing to possible mineral imbalances are unlikely. The

consequences in lowering the risk of colon cancer, possibly other intestinal disease and even early diabetes^{17,18} would be appreciable if not "dramatic". Please, Dr Yudkin, be objective.

Yudkin's answer

SIR - My article, to which Weisburger and Reddy refer, was a review of two recent publications, both entitled Medical Aspects of Dietary Fibre. One of these was a report of the Royal College of Physicians, which had this to say about fibre and colon cancer:

"There are reasonable grounds for the statement that, in genetically susceptible persons, large bowel cancer could be favoured by a fibre-depleted diet, but other explanations for the commonness of this cancer in Westernized countries are possible. Definite conclusions must await the identification of the carcinogen(s) and the study of environmental factors on its production.'

As the references mentioned in the report make clear, the authors made at least as exhaustive a study of the literature as did Weisburger and Reddy in their letter; they also include the papers published by these workers.

The RCP authors, however, were clearly not as convinced that this evidence was conclusive as are your correspondents. In suggesting that I am not objective in my account of the role of dietary fibre in preventing colonic cancer, Weisburger and Reddy are really saying that the RCP itself was not objective when writing its report.

JOHN YUDKIN

London NW3, UK

NEWS AND VIEWS

The longest synthetic gene. . . so far

LESS than two years ago, an attempt to synthesize a human interferon gene would have literally been impossible. For it is just two years since nucleotide sequences of interferon genes were first determined by using reverse transcriptase to make DNA from messenger-RNA molecules taken from cells induced to produce interferon. Since then, similar DNA copies of mRNA have made it possible to show that there is a whole family of interferon genes in the human genome - several corresponding to leukocyte interferon (the α variety) and fewer corresponding to fibroblast interferon (called β) and the more elusive immune interferon (y). Inevitably, the amino acid sequence of each of these interferons has not vet been worked out directly, by chemical analysis; instead, the protein structure has mostly been inferred by applying the genetic code to the sequence of nucleotides in the gene. So it is, to say the least, a technical triumph that a group assembled by ICI should now have carried through the total synthesis of a human interferon gene (see Edge et al., p.756).

This gene is the largest so far synthesized, no fewer than 514 nucleotides long. Given that it has been necessary to string together the nucleotides of both the complementary DNA strands, more than 1,000 nucleotides have been assembled in a predetermined way.

The chemistry of the synthesis is more easily described than carried out. The starting point is an initial nucleotide coupled to a polyacrylamide resin. Further nucleotides are added in pairs, by means of a coupling agent in anhydrous pyridine. and the authors say that the time taken for each cycle is a mere hour and a half. At that rate, ambitious people might calculate, it should be possible to assemble 5,000 nucleotides in a year, or a whole genome in ..., well, a few centuries. Calculations such as these show that even the modifications of DNA-synthesizing techniques worked out by the ICI group fall a long way short of assembling whole genomes.

Indeed, as now described, short sections of each strand 15 or more nucleotides in length have to be made separately so as to keep the yield of the synthesis respectably high, and then short pieces of the double helix assembled before being joined

together in the complete gene. That the gene is complete has been shown by its incorporation into a plasmid, its amplification and subsequent analysis. Edge and his colleagues do not say whether their plasmids have been able to direct the synthesis of proteins — and if so, what they are — but something is produced, for a further report on its biological activity is promised. It would be a great surprise if the product were not α -interferon.

The gene now synthesized is not however a naturally occurring gene but an analogue, designed so as to simplify the synthesis, but also to avoid combinations of neighbouring nucleotides that may impede expression of the gene in its unnatural environment of the plasmid. It should make one of the versions of α -interferon and, with luck, should do so more efficiently. But it would be sheer good fortune if the gene now synthesized turned out to be a superabundantly efficient interferon gene. The importance of this development is not the gene itself, but the demonstration of the technique. It is a little like climbing Everest, known to be easier the second time.

But these days, it is possible to buy machines that will automatically assemble nucleotides in some predetermined sequence. What can be so special about the synthesis of this artificial gene? For one thing, the simple assembly of a score or so of nucleotides is only half the battle. Purification is a tedious and even uncertain business. Prudent people make sure that the nucleotide sequence they have made is indeed the one they set out to make by subsequent analysis. But the most important need in the construction of a largish gene is an intelligent strategy for deciding what pieces of the gene to make, and in what order to assemble them. The use of computers to spot sequences in the target gene that might cause trouble during its assembly is also obligatory.

This does not mean that the work now reported is simply a technical tour de force. In the past few years, synthetic pieces of genes have been widely used in several different ways — as probes for finding within some intact genome a piece of genetic material containing some particular sequence, for example. Those

whose business is to insert foreign genes into plasmid DNA increasingly find it safest to resynthesize the ends of the genes back to the nearest convenient restriction site so as to ensure that nucleotides are not lost when the tails needed for ligation to the plasmid DNA are added chemically. Fashioning pieces of DNA expected to have important functions such as those acting as sites for the promotion of replication has also become fashionable and valuable. But for a group with its roots in the pharmaceutical industry, it must be especially pleasing that it is now possible to plan systematically to vary the constitution of a gene for the sake of the variations of protein structure that result. Is there just a trace of nostalgia in the statement that "classical medicinal structure-activity analysis should [now] be possible with large peptides"?

The prospect is exciting. There is already ample evidence, derived from the experience of traditional pharmacology, that natural products can usually be modified to make more efficient drugs. The changes rung on the structure of the naturally occurring antibiotics in the past several decades are a sign of that. The interferons promise to be a nightmare for pharmacologists - whatever their biological effects, unspecificity seems to be their common characteristic. So it is natural that in the past few months, there has been great interest in hybrid molecules of interferon — one end from one and the other from another. Now it should be possible to set about making more subtle modifications, not those that depend on where some restriction site within the gene happens to fall. The result should help throw light on the functions of different parts of the interferon molecule. Yet improving on naturally occurring interferon is bound to be a daunting task. While reliable biological assays of the effectiveness of molecules related to interferon are few and far between, and while the efficiency with which interferon genes embodied in plasmids yield protein product is as low as at present, it would be hoping for too much that the uncertainties that abound in the genetic engineering of medicinal interferon will quickly be cleared

Saturn's rings

MUCH of the interest in Saturn's rings during the impending close encounter of Voyager II will centre on explanations of the structure of the ring system, involving either resonance with the major planetary satellites or the effects of smaller satellites co-moving with the rings. The excitement may obscure the argument due to Joseph E. Avron and Barry Simon (*Phys. Rev. Lett.* 46, 1166; 1981) published earlier this year that the radial structure of the rings of Saturn may simply reflect the instability at certain radii of solutions of the full many-body problem.

The argument is simple, although incomplete. Ignoring all but Saturn and one ring particle, supposed of negligible mass, orbits with all possible periods of revolution between that of the orbit that grazes the equator of the planet and infinity are stable. No more complicated version of the problem is, however exactly soluble. The general equation of motion is, however, $\ddot{\mathbf{r}} = \mathbf{F}(\mathbf{r}(t))$ where the force-function \mathbf{F} , a vector function, itself entails a solution of the many-body problem of Saturn, together with its substantial satellites and, for that matter, the Sun.

Approximations are evidently necessary, one of which is that the true force-function should be represented as the sum of forces within the equatorial plane and those perpendicular to it whereupon it is also sensible to represent the radius vector as the sum of a vector in the plane and another perpendicular to it with the form w(t). To a first approximation, supposing w to be small, the result is the need to solve a Schrodinger equation with (at best) a quasi-periodic potential. This simplest version of the problem of the motion of Saturn's ring particles can, in other words, be approximated to by the still insoluble problem of knowing what states are accessible to an electron in a quasiperiodic electric potential.

The upshot is that many periodic solutions of the simplest equations are unstable and therefore, over a substantial period of time, untenable. But which are they?

Avron and Simon did not pretend, in their paper published at the end of April, to be able to calculate the periods of the orbits that would be unstable (and thus the position of the gaps in Saturn's rings). Instead, they argued that even the simplest approximation to the manybody problem gives rise to Schrodingerlike equations whose solutions are restricted. Some orbits are possible and stable. Others are not. Avron and Simon surmise that between the rings, stable orbits should be distributed in radius as the numbers in a Cantor set — sparsely but not isolated.

Solar spin variation

from David W.Hughes

ONE of the most striking features of normal main-sequence stars is the great difference in the angular momentum per unit mass between the early and late types. There is a sharp drop at spectral type F, as shown in Fig.1. Some braking process must act preferentially on stars of low mass.

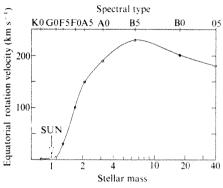

Fig.1 The equatorial rotational velocity of main-sequence stars plotted as a function of spectral type and stellar mass (measured in units of the solar mass).

Schatzman (Ann. Astrophys. 25; 1, 1962) pointed out that braking would occur if the gas emitted by a star was magnetically constrained to co-rotate with the star out to distances that were large compared with the stellar radius. Under these circumstances a small amount of mass loss would yield a proportionally much greater loss of angular momentum, simply due to the effective increase in the moment of inertia of the outflowing gas. The efficiency of the braking depends on the strength of the subsurface convection which is itself closely related to the mass of the main-sequence star. This convection is also responsible for the surface activity, such as sunspots, for the corpuscular emission associated with these spots and for part of the general magnetic field of the

Edward H. Geyer of the Hoher List Observatory, University of Bonn, has studied the braking of solar rotation by magnetic activity and his conclusions have recently been published in *The Moon and the Planets (24, 399; 1981)*. Geyer compares the Sun with the primary component of the eclipsing binary XY Ursae Majoris (UMa). This is a solar-type star, with

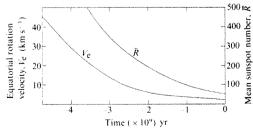

similar mass but about 50 times more magnetic activity than the Sun. The binary has an orbital period of 11.5 hours, the components are close and suffer considerable tidal deformation. The XY UMa primary has a spot cycle of about 3.7 years, in comparison with the solar cycle of 11.04 years. At maximum the XY UMa primary has about 20 per cent of its surface covered in spots. XY UMa is spinning quickly - the braking that would lead to a loss of rotational angular momentum is counteracted by a replenishment from the much larger orbital angular momentum of the secondary by a tidal feedback mechanism.

The rotational angular momentum of a star on the lower main sequence determines its spot activity. As magnetic brakes have been applied to the Sun for at least the past 4.6×10^9 years, the Sun must have been spinning faster and showing more magnetic activity in the past. Geyer assumes that the loss of angular momentum takes place at the same heliographical latitudes (5° to 40° north and south) as the maximum spot activity; this maintains the differential rotation. He also assumes that the mass loss is less than a few per cent of the present mass and that the radius has remained constant. He concludes that the angular velocity and the spot activity both decay exponentially, with a mean lifetime of 1.55×10^9 years. Today the mean sunspot number, \bar{R} , is 51 ± 35 and the equatorial spin velocity is 2.02 km s-1. The values of these quantities in the past are plotted in Fig.2.

The effects of these changes are interesting. In the past, the faster spinning Sun would be more oblate, which would perturb the orbital motion of the inner planets. The greatly enhanced sunspot activity must have influenced the evolution of life on the Earth. The increase in solar particle flux and extreme ultraviolet radiation would disturb the terrestrial magnetic field and the original atmosphere; the production rates of carbon-14 and tritium would be higher than they are today; and the atmosphere would be enriched in ³He.

Geyer concludes that evolution of life and its transference from the protecting water to the exposed land were governed by the solar activity and its decay with time.

David W. Hughes is in the Department of Physics, University of Sheffield.

Cosmochemistry and the origin of life

from Geoffrey Eglinton, Ann Henderson-Sellers and Stephen Moorbath

At a recent NATO conference* on 'Cosmochemistry and the origin of life'. Ponnamperuma (University of Maryland) summed up the overall picture by showing that there is a continuity stretching from space through to the present in terms of the formation of organic molecules and those that are found in present-day living organisms, and held that this is the natural course of events. Viola (Indiana University) started with the 'big bang' and then discussed nucleosynthesis and the abundance of the elements, particularly those essential to life. He also discussed the life cycle of stars and models of the Universe - salutary topics which should be compulsory course work for all scientists at some stage in their careers. Greenberg (University of Leiden) and Irvine (Chalmers University, Sweden) continued with details of the nature. composition and distribution of the interstellar dust and gas medium, and emphasized the enormous reservoir of organic molecules and most basic raw materials of life known to exist in interstellar space. Conference participants thought it unnecessary, at this state of our knowledge, to invoke Panspermia - the seeding of our planet, at any stage in its history, by life from extraterrestrial sources. In this much publicized context the conference generated neither science fiction nor science friction.

NASA's spaceship Enterprise, ably piloted by de Vincenzi (NASA Headquarters), took us on a tour of the Solar System, culminating in an account of the Mars Lander's biological experiments. Initial optimism and excitement soon gave way to the more sober realization that surface oxygen release could be better accounted for by presence of labile, active inorganic oxides in martian soil than by biological activity. Prospects for contemporary life on Mars are bleak, but perhaps in its originally airier and wetter manifestation it might have temporarily harboured the seeds of early life. The rest of the Solar System is decidedly no place for protoplasm!

The conference then rapidly came down to Earth. However improbable it seems, life and mind flourish, and some 4 billion years separate the earliest replicating organic molecules from the deliberations of the present conference. After presenting an inventory of terrestrial surface carbon, Henderson-Sellers (University of Liverpool) noted that, without its hydrosphere and biosphere, the Earth would be very similar to Venus, where carbon dioxide is not tied up in carbonate rocks. She, as well as Ponnamperuma, summarized much of

the evidence that the atmosphere of the early Earth was dominated by carbon dioxide, water, nitrogen and possibly some carbon monoxide, and not by ammonia, methane and hydrogen as was once widely believed. The bulk of the hydrosphere was undoubtedly present from very early prebiotic times. Ample energy sources, including electrical discharges, ultraviolet radiation, radioactivity and volcanic/geothermal heat, were available on the early Earth to foster complex, prebiotic organic syntheses from relatively simple mixtures of volatiles and gases, with clay minerals as a likely base for the earliest biotic processes.

Moorbath (University of Oxford) showed that isotopic dates on early Precambrian sediments containing biological or molecular fossils could frequently be obtained from stratigraphically closely associated igneous rocks, and more rarely from the sediments themselves. Algal stromatolites and other simple cellular structures were known from sediments probably as old as 3.5 billion years, although in some cases there is a worrying stratigraphic gap between the sediment and the dated igneous rock. Whether the Isua metasediments of West Greenland, dated at about 3.8 billion years, contain biogenic markers is still a matter of controversy. Schidlowski (Max-Planck-Institut, Mainz) is convinced from detailed carbon isotope studies that Isua carbonaceous sediments represent a 3.8 billion year-old record of biological activity. There is a continuity of the δ^{13} C record from the present back to Isua times, and yet the Isua rocks also exhibit a marked shift in δ^{13} C which may result from their strong metamorphic overprint. Indeed, some workers claim that the δ^{13} C record of the Isua rocks has been achieved by metamorphism alone. Walters (University of Maryland), after painstakingly pyrolizing 27 Isua graphite samples, observed no trace of biogenicity, with one possible exception. The metamorphism was certainly intense enough to erase any biogenic evidence.

Ochiai (University of Maryland) pointed out that bioinorganic chemistry was essential for understanding chemical evolution. Many trace metals, such as Fe, Cu, Mo, Mn, Co, Zn, Ni, Cr and V, form complexes which catalyse organic reactions considered essential for life processes. He also discussed the problem of the major Precambrian Banded-iron Formations, ranging in age from about 3.8 to 2.2 billion years, and regarded by many as biogenic markers in the sense that their precipitation may have required oxygen released from marine organisms, in the virtual absence of atmospheric oxygen. This 'iron age' was followed at about 1.5 billion years onwards by copper sulphide deposits — the 'copper

age'. Before this, prevailing redox conditions would not permit copper to appear in a dissolved, mobile state. A tentative correlation might be made between the sudden appearance of the copper deposits and the distribution of copper enzymes in present-day organisms. In this view, the copper superoxide dismutase is a later and more efficient development than the manganese and iron superoxide dismutases.

From the organic record in more recent sediments, Eglinton (University of Bristol) produced abundant evidence that molecules can retain a high degree of structural and stereochemical specificity over hundreds of millions of years if they are not exposed to raised temperatures or subject to oxidation or microbial attack. Specific biological marker compounds, or 'chemical fossils', can be interpreted in terms of the palaeoenvironment. The thermal history of a sediment can also be understood in terms of epimerization, aromatization and carbon-carbon bond cleavage reactions observed in samples with different burial histories. Of particular interest is the possibility of relating the molecular lipid record to microbial activity. Thus the archebacteria display unusual membrane lipids which may provide a clue to their activity during the Precambrian.

All participants agreed that there is an urgent need to continue the search for ancient, unmetamorphosed sediments earliest from the accessible Precambrian. so that micropalaeontologists, inorganic and organic geochemists, clay mineralogists, geologists and geochronologists can work closely together towards a progressive characterization, through geological time, of the biological record in the rocks. Recent geological work clearly shows that the earliest known (about 3.8-3.5 billion year) sedimentary and volcanic rocks characterize a depositional environment which is totally compatible with conditions now widely regarded as favourable for the earliest life on Earth. Of course, one big question was forcibly put to us by the students - "when did life begin?". The best bet was 4.0±0.1 billion years ago. The origin of life could be even older, but most people agreed that it was unlikely to be vounger.

Altogether, it was a creative and original Study Institute, which looked as much into the future as into the past. Is it just conceivable that a conference on the same topic is at this moment being held somewhere else up there in the night sky?

Geoffrey Eglinton is in the School of Chemistry, University of Bristol; Ann Henderson-Sellers is in the Department of Geography, University of Liverpool; and Suphen Moorbath is in the Department of Geology, University of Oxford.

Holocene wiggles

from R.W. Fairbridge

THE trouble with time series relating to geophysical and climatic phenomena is that the instrumental data base is often less than 100 years long, whereas many of the suspected planetary steering mechanisms operate on quasi-periodic wavelengths in excess of 103 years. More precise chronostratigraphical methods are needed when looking for correlations in the area of celestial mechanics where hindcasting may often be estimated with a year-to-year accuracy, for at least 104 years. The customary geological dating technique in this age range, radiocarbon, commonly suffers from an accuracy of only ± 250 vears or so.

Some new developments discussed at a recent meeting* promise to provide a yearto-year chronology dating back to beyond 13,000 BP, with a precision of ± 1 year. First, there is the old varve chronology of De Geer. To begin with it suffered from a 'bad press'; people did not feel much confidence in a simple thickness counting. But over the past two decades the Swedish scientists and government have considered it important enough to spend several millions of kronor proving the accuracy of the method (within the error limits of radiocarbon), and re-counting the old series. I. Cato (University of Uppsala) recently completed the count up to AD 1980 and incidentally has shown that it is the annual peak flood (1-2 days) that corresponds to the maximum thickness of the

summer varve. Soon it will be possible to state the peak flood years in south and central Sweden for the past 13 millennia.

Second, the ¹⁸O/¹⁶O analyses of ice cores taken in Greenland and Antarctica are being extended and 'massaged' to generate far more precise time series than at first seemed possible. At the meeting, C. Langway (SUNY, Buffalo) described some of the techniques and W.D. Hibler (Cold Regions Research Laboratory, New Hampshire) demonstrated an approximately 20 year cycle recognized in both ice cores and tree rings since AD 530. W. Dansgaard (University of Copenhagen) recently reported1 some of the ice-core problems and solutions. Absolute (year-toyear) counting now goes back nearly 2 millennia and is rapidly being extended. Hammer, Clausen and Dansgaard² have described an ingenious pH-measuring device that records the acid layers in the ice cores that develop as a result of volcanic gas 'rain-out'. As Clausen (University of Copenhagen) demonstrated at the meeting, it is now possible to identify many historically known volcanic eruptions and thus independently confirm the layer counts. When combined with the oxygen isotopes, this gives a climatic reading.

The third category of Holocene wigglyline time series concerns dendrochronology. In contrast to varves and ice cores that reflect regional climatic trends, tree rings initially reflect only individual trees, but with regional studies and sophisticated analysis this material also furnishes valuable climatic series. In addition, and most importantly, the tree rings provide a fourth wiggly line — the variations in the radiocarbon flux — from which come the cosmic ray and solar wind fluctuations. We now have a picture of solar activity that takes us back nearly 8,000 years³, and this limit can be extended to beyond 13,000 BP as soon as some floating chronologies can be tied in.

The problem of floating time series is a speciality of D. Schove (St David's College, UK). There are numerous varve and dendrochronological series from Europe, North America, South America and Asia that have not been tied in to a known datum. If these long runs can be spliced together we shall get a year-by-year record of climatic events (local, regional and, we hope, global) going back nearly 14,000 years. Schove works on the principle that most of the wiggles represent local climatic 'noise' and may have little global significance, but certain key years disclose very remarkable 'spikes' which recur in distinctive patterns. The methodology works very well with tree rings, varves and, on a longer time scale, geomagnetic reversals.

Simplistic correlation attempts with the 11 year sunspot 'cycle' have often run aground, but analyses of phase changes and interactions with other cyclic effects can be rewarding, as reported by J. Harlin⁴. Schove⁵ has considered the fact that the quasibiennial cycle (26 months). when superimposed on a powerful annual signal, may eventually lead to a 3 year jump. Inasmuch as the sunspot maxima fluctuate markedly, the combined effects result in distinctive patterns for any given century. Although the astrophysical and meteorological mechanisms are still shrouded in mystery, the pattern system seems to work, providing the approximate time span is known — and this link is provided by radiocarbon and other geological techniques. Particularly important time series that may soon be tied in by these 'teleconnections' are the Finnish varves, described by M. Saarnisto (Oulu University, Finland), and those of southern Germany by J. Merkt (University of Hannover). Schove has proposed teleconnections in the mid-Holocene between America (Bristlecone), Ireland, the Crimea and Anatolia⁶.

Hints about the long-term variables were to be found in the palaeomagnetic records displayed at the conference by K. Creer (University of Edinburgh). Systematic coring of undisturbed lake beds from different parts of the world is now beginning to bear fruit. Both inclination and declination show systematic fluctuations with a quasi-periodicity of the order of 1,000-3,000 years. A variable rate of westerly secular drift introduces a longitudinal lag in dates, and at the same time warns of the variability in the outer core dynamics.

Inasmuch as both the geomagnetic field and the solar wind (a magnetized plasma

^{*}A conference on 'Holocene Correlation' was held on May 1, 1981 at the Warburg Institute, University College London, under the auspices of the UNESCO-supported International Geological Correlation Programme no.158. The meeting was jointly chaired by Dr. Derek Schove and Professor Rhodes W.

100 years ago

NOTES FROM THE MALAY
ARCHIPELAGO

A correspondent in Java sends us the

The cattle plague has been raging in the west end of Java, Bantam, the Preanger, and Batavia residences — during the west monsoon (now finishing) with redoubled vigour. It has now abated a little (after four years—it may well do so, from want of victims) in these parts, but is extending eastward, its appearance in Krawang being the most alarming. The authorities have decided upon making a double-fence right

across Java at its narrowest part. This means a line from somewhere about Cheribon due south. In the interval — a considerable one — between the two fences, no cattle will be allowed to pass or exist.

There is a bird (native name Jallak) which follows the buffaloes about and perches on their backs. Query, can this bird have anything to do with the spreading of the plague? If so I don't see what Government can do. They can't fence him out.

In all the parts where the cattle-plague has raged the most awful fevers have been the result amongst the native population. In Bantam alone 50,000 died in 1880. In the Preanger and Batavia the death-rate was also very high. There is no doubt whatever that this is due to the imperfect interment of the carcases. The Government says it is due to the wet season; but this is a lame excuse, for why is there no fever elsewhere? In the wet season it is, of course, worse, for the heavy rains cause more miasma.

From Nature 24, 25 August, 399, 1881.

R. W. Fairbridge is Professor in the Department of Geological Sciences, University of Columbia.

flow) modulate the incoming galactic cosmic rays, the radiocarbon flux, monitored by the tree rings, can now be related in part to core dynamics. A new monitoring isotope, beryllium-10, was discussed at the meeting by G.M. Raisbeck (Orsay, France). This isotope is also formed in the atmosphere by cosmic ray collisions and within a year deposited on the Earth's surface. It can be measured most conveniently in ice cores, thereby providing not only a way of cross-checking the 14C data, but also of extending the cosmic radiation record back for perhaps up to 105 years.

R.W. Fairbridge (Columbia University) displayed colour slides of the field evidence illustrating how the cyclicity of highlatitude storminess cycles on the Hudson Bay seems to reflect a 45 year 'Double Hale' solar cyclicity7. He then reviewed new unpublished works that demonstrate solar-planetary periodicities from the Permian period, 250-280 million years ago: first, from an anhydrite series in New Mexico (R.Y. Anderson, University of New Mexico); second, from an evaporite series in the Ural Mountains, USSR (I.

Vulis); and third, from a varve series in Brazil (Rocha-Campos). The astonishing thing is that they all display what seem to be the same periodicities that occur in the Holocene, which, if nothing else, would appear to dash the hopes of velikovskian catastrophists.

Pre-equilibrium processes in nuclear reactions

from P.E. Hodgson

THE processes that take place when a fast nucleon (10-100 MeV) interacts with a nucleus are quite well understood, but there are many detailed features that require further study. The incident nucleon first collides with a single nucleon or perhaps a cluster of nucleons in the target nucleus. The products of this collision have a high probability of escaping from the nucleus, particularly if the collision takes place on the periphery. This initial interaction takes place rapidly, in the time it takes for the incident particle to traverse the target nucleus, typically about 10-22 seconds.

The particles from this first collision that do not escape from the nucleus undergo further collisions until all their energy is transferred to the compound system. The energy is shared among the nucleons until eventually, by statistical fluctuation, a nucleon or group of nucleons receives enough energy to escape; this continues until the energy falls below the particle emission threshold. The residual nucleus eventually attains its ground state by y and B decay. The statistical processes by which the compound nucleus loses its energy take much longer than the direct process, typically about 10-16 seconds.

The direct and compound processes are quite well understood theoretically, so the corresponding cross-sections can be calculated with some confidence. The simplest direct process, elastic scattering, can be calculated by the optical model, and inelastic scattering by the coupled channels or distorted wave formalism. Nucleon transfer reactions can be treated by the distorted wave Born approximation, and the probabilities of emission of various particles from the decay of the compound nucleus can be calculated using the Hauser-Feshbach theory with the transmission probabilities obtained from optical model analyses of elastic scattering.

The direct and compound processes usually both contribute to each reaction and the total cross-section may be obtained

by adding them incoherently. This may be compared directly with the measured crosssections, after the latter have been energyaveraged to remove the fluctuation in the compound nucleus cross-section.

Such calculations are generally fairly successful at lower energies, but at higher energies additional processes can occur and have to be accounted for. In particular, it is possible for particles to be emitted after the direct process but before the nucleus has attained statistical equilibrium. These preequilibrium or pre-compound particles can be recognized experimentally and their cross-sections have been calculated using several different models.

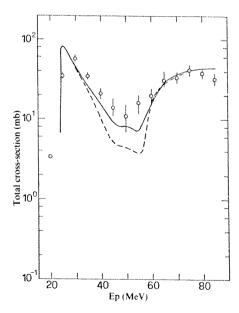

Fig.1 The excitation function for the 50Ti(p,2p2n) 47Sc reaction compared with exciton model calculations. The dashed line shows the result of a calculation without the pre-equilibrium particles and is clearly inconsistent with the data. From ref.3.

P.E. Hodgson is in the Department of Nuclear Physics, University of Oxford.

The particles emitted in the direct, preequilibrium and compound stages are characterized by their differing energy and angular distributions. Direct particles are emitted predominantly in the same direction as the incident particle, with similar energies, whereas compound nucleus particles are emitted in all directions, equal numbers forwards and backwards, and when the final states merge into a continuum have a characteristic maxwellian energy distribution. Preequilibrium particles tend to be emitted forwards, and are generally more energetic than those from the compound nucleus.

To calculate the cross-section for preequilibrium emission, the interaction process is considered to take place in several stages. The first stage can lead to the emission of direct particles, or to the excitation of a particle-hole pair. In the second stage further interactions can occur, which can lead to the excitation of further particle-hole pairs, and so on until finally the compound nucleus is formed. At each stage in the excitation process it is possible for pre-equilibrium particles to be emitted.

This process has been formulated mathematically, enabling the pre-equilibrium cross-sections to be calculated. One type of theory due to Blann¹, Griffin², Gadioli³ and others gives semi-classical expressions for the cross-sections in terms of the basic transition matrix elements that express the probability of going from one stage to the next. Such theories have been used to calculate the cross-sections of many different reactions and a typical comparison with experiment is shown in Fig.1. In this work the cross-section is determined radiochemically, so it is not possible to distinguish between the (p, a) and the (p, b)2p2n) reactions. The former reaction is favoured energetically and is responsible for the first peak, and the latter for the second. The two curves are calculated with and without the pie-equilibrium contribution, and comparison with the experimental data shows the presence of these

More recently, a quantum-mechanical theory has been developed by Feshbach, Kerman and Koonin⁴, and numerical calculations made by Colli-Milazzo and collaborators⁵. This gives both the angular and energy distributions of the emitted particles, and extensive comparisons with

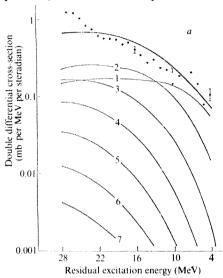

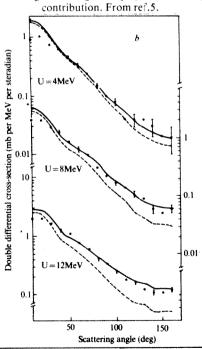

Fig.2 a, Energy spectra for the 48Ca(p,n) reaction at 45 MeV at 90° as a function of the energy of the residual nucleus. The individual curves show the contributions of the various multistep processes. The excess of particles at higher excitation energies, corresponding to lower emission energies, is attributed to multiparticle emission. b, Differential crosssection for the 90Zr(p,n) reaction at 45 MeV showing the single-step (dashed line)

the experimental data for (p,n) reactions from 25 to 45 MeV on nuclei from calcium to tin show good overall agreement. An example of such a comparison is given in Fig.2, showing the contributions of the one-step (direct) and various multi-step (pre-equilibrium) processes.

Calculations of the contributions of multi-step processes to proton inelastic scattering have been made by Tamura and Udagawa6 using an extended version of their distorted wave formalism. This theory is also able to give a good overall account of the measured cross-sections.

There is still much work to be done to justify and establish the accuracy of some of the assumptions and approximations made in these calculations, and it will be important to test the different theories by using them to analyse the same reactions.

Mammal tracks on mountain slopes

from Robert M. May

ONE of the many differences between the Victorian Age and our own is written in the paths in the English Lake District. Today's path from Wasdale Head to Sty Head follows the direct line (and the steepest slope) across the shoulder of Great Gable; few use the nineteenth century path that zig-zags in a more leisurely and scenically varied way along the side of Lingmell Beck. From the head of Langdale one can ascend to Angle Tarn directly by the stoney boredom of Rossett Gill, or more slowly via the sweeping switchbacks of the almost vanished pony track.

Faced with these choices, the behavioural ecologist may be prompted to ask which paths are energetically optimal. Some pertinent laboratory and theoretical studies are due to Taylor, Caldwell and Rowntree (Science 178; 1096, 1972). These authors began by observing that the energy needed to elevate an animal to a given height is proportional to its body weight, whereas the animal's power output available to perform this task tends to be roughly proportional to its surface area; hence the energy costs of moving uphill (compared with moving at the same speed on level ground) are relatively greater for larger animals. Turning to the laboratory, Taylor et al. substantiated this analysis by showing that movement up a 15° incline at 2 kmh⁻¹, compared with running on level ground at the same speed, resulted in a 40 per cent increase in oxygen consumption for a chimpanzee, but only 1-2 per cent for a mouse. Extrapolating their experimental results, they estimated that running vertically at 2 kmh-1 would increase the oxygen consumption of a 30 g mouse by 23 per cent, of an 18 kg chimpanzee by 190 per cent, and of a 1,000 kg horse by 630 per cent.

This work helps explain why squirrels can run up trees at much the same speed as they run from tree to tree, and why fell

Robert M. May is Class of 1877 Professor of Zoology at Princeton University.

runners are lean. But it sheds no direct light on whether largish animals should ascend hills directly, or obliquely in zig-zags. Indeed, an analysis along the lines of Taylor et al. suggests that the energy involved (in addition to baseline metabolic costs) in getting an animal of mass m to the top of a mountain of height h is simply mgh, independent of the angle of attack. A more gradual ascent, at an angle of ascent θ relative to the horizontal, involves a relatively smaller cost of moving up the slope (by a factor $\sin \theta$), but takes longer to reach the top (by a factor $1/\sin\theta$); the two effects cancel each other out.

Reichman and Aitchison (Am. Nat. 117; 416, 1981) have recently made a most interesting attempt to find out how animals actually do ascend or traverse hillsides in nature. To this end, they measured trails left in the snow on hillsides in the southwestern United States, by various mammals. By choosing fresh snow that covered existing trails, these authors hoped to find trails that had been made at the discretion of the individual animals; records were compiled only for situations where the animal appeared to be moving freely up a slope, rather than wandering from one feeding spot to another, or fleeing pursuit. Each mammal was identified by its footprints, and the average weight for that species assigned to it. In this way, Reichman and Aitchison compiled data for some 130 individual animals, of 22 different weights ranging from a 0.025 kg mouse to a 680 kg buffalo.

Reichman and Aitchison defined the 'trail angle' to be the angle between the actual trail on the hillside and the horizontal; thus an animal proceeding directly up the mountain at the angle of steepest ascent has a trail angle of 90°, while an animal moving around the hillside at a constant elevation has a trail angle of 0°. This trail angle has a slight, but statistically very significant, propensity to be smaller for heavier animals. The negative correlation is even more striking if one plots the maximum trail angle observed for any one body size against the weight of the animal. As Reichman and Aitchison observe, "it seems intuitive that the trail angle used by animals should decrease with increased body size, and the field data support this outcome".

A clearer test of the basic ideas, however, is provided by examining the correlation between trail angle and the slope of the mountain itself. The analysis outlined above suggests that, to a first approximation, the energy costs are the same whether one ascends obliquely or directly. This would lead to the expectation that the trail angle is uncorrelated with the slope of the mountain. Alternatively, for animals in a hurry to get to their destination, we might often expect a direct ascent, and hence trail angles of 90° irrespective of the mountain slope. This latter expectation may be modified for large animals on steep slopes, where the metabolic costs of sustaining uphill motion may become prohibitively large; that is, there may be a maximum slope, $\theta_{max}(m)$, beyond which an animal of mass m cannot sustain uphill motion. Such a θ_{max} will decrease with increasing body weight; on an almost vertical hillside, mice and squirrels may scamper up directly (trail angle of 90°), but heavier animals are likely to ascend obliquely at a trail angle of about θ_{max} . Of course, questions of local topography and, above all, the purpose of the journey would complicate all this.

On this basis, I would expect that, when Reichman and Aitchison's data (embracing all body weights) were plotted in the form of trail angle versus mountain slope, there would either be no correlation at all, or else a propensity for trail angles to be random at low mountain slopes, and for steep trail angles to be rarer at high mountain slopes. In fact, such a plot reveals a puzzling tendency for trail angle to be approximately proportional to mountain slope. Remarkably, essentially no animals — not even the mice — are ascending shallow hills directly (at trail angles of 90°).

It seems likely that the animals making these tracks were, by and large, simply wandering across or skirting the shallow-sloped mountains. (Though why they should be doing so almost exclusively at low trail angles remains a mystery to me.) On the steeper hillsides the tracks may be telling us more about energetics of moving up a slope, but even here it could be that the geometry of the tracks depends mainly on why the animal was going from A to B, rather than on anything else.

In short, the study by Reichman and Aitchison is a very original and thought-provoking one, but I think the next steps will need to include consideration of the behavioural ecology of the animals in question. If we seek to plot our paths through the hills according to principles of optimality rather than sheer delight, the current literature remains unhelpful.

HLA genes, immunoglobulin genes and human disease

from Ken Welsh

THE human lymphocyte antigens (HLA) were recently described by one of my colleagues as simple equivalents of the ABO system found on all cells except red cells. In fact the HLA system comprises a group of several hundred genes located on the short arm of chromosome 6 but the only gene products of this region well recognized in the human HLA-A.-B.-C.-D and -DR and complement components C2, C4 and Bf. All these are polymorphic to a greater or lesser extent and a range of products of this region is expressed on most lymphoid cells.

Almost ten years ago at an International Transplantation meeting in San Francisco, participants were given large badges inscribed with the words "Are you my HLA type?". At that time the close association between HLA-B27 and ankylosing spondylitis (AS) had just been rumoured1,2 and prevailing evidence suggested that good HLA matching of donor and recipient would solve the major problems of transplant rejection. The badge implied not only hope for transplantation but also that by suitable selection of partner, major diseases could be avoided in the next generation. Now, although hyperacute rejection has been virtually eliminated, we are no closer to predicting acute or chronic rejection on the basis of HLA type and the closest HLA and disease association is still that between HLA-B27 and AS. But the years of consolidation and continual searching are beginning to be rewarded; at the recent European Dialysis and Transplantation meeting in Paris we heard how revisitation of red cell types and skin testing techniques coupled with precise HLA cross-matching and HLA-DR typing have again given us hope for success in transplantation.

On the question of HLA and disease, a paper published in this week's issue of Nature (p.768) by Uno and colleagues may provide the necessary break in the flood wall and enable us accurately to identify individuals at risk from certain major diseases. Several cracks had already appeared in the wall, so a break is not unexpected.

The first came with the finding that a combination of HLA type and acetylator status can identify with very high reliability those women who will develop auto-immune complications if treated for hypertension with the drug Hydrallazine³. HLA-DR4-positive, slow acetylator females always develop the complication;

Ken Welsh is in the Tissue Typing Laboratory at Guy's Hospital, London.

DR4-positive, slow acetylator males will escape unless given high doses of the drug. About 8 per cent of hypertensive patients treated with Hydrallazine develop a lupuslike complication. In the normal population about a quarter are DR4 positive, and half are females and half are slow acetylators, giving us an expected complication rate of about 6 per cent. Occasional DR4-positive males on high drug doses, DR4-positive rapid acetylator females and DR4-negative slow acetylator females develop the complication and account for the small discrepancy. This discovery shows how a combination of apparently unrelated genetic 'markers' can be used for accurate identification of a population at risk.

Two other recent discoveries bear directly on the work of Uno et al. The first was that the relative risk of developing chronic active hepatitis was 11.7 for those people having HLA -B8/DR3 and 2.3 for those having a particular immunoglobulin allotype4 - a genetic marker expressed on antibodies. As in the Hydrallazine lupus story, a combination of the two markers is associated with a significantly greater risk, in this case 40-fold greater, than if neither marker is present. The second discovery5 was that relapse in hyperthyroid Graves' disease can be predicted by a combined analysis of HLA -DR3 status and the level of thyrotrophin receptor antibody at the time of drug withdrawal. The prediction in this case was accurate in 62 out of 65

An alternative approach to identifying individuals at risk would be to use a combination of genetic marker and family studies. For example, if incidence of a disease is 1 in a 100 in the population and the disease is associated with HLA-B27 (which is present in about 10 per cent of the population), then even if all the people who get the disease are B27 positive it still means that only 1 in 10 B27-positive people are at risk. However, if the disease is already present in a family, this risk rises very dramatically for B27 family members.

Uno and co-workers have combined these two approaches in their study of Japanese families having more than two first-degree relatives affected by Grave's disease. In the data presented, 32 out of 33 children suffering from this disease carried a particular HLA and IgG-linked gene combination. The single child having only the IgG-linked susceptibility could be explained by a recombination between the HLA marker gene and a hypothetical HLA gene actually responsible for the disease. A more complete HLA typing involving SB

antigens, complement allotyping and additional enzyme markers would clarify the point.

Although in the face of the evidence presented one tends to think of tissue typing at birth (to predict the occurrence of autoimmune disease) or perhaps even before one goes to the computer dating service, there are practical scientific reasons for being cautious. For example, Uno et al. selected only 15 of the 30 families studied for inclusion without saving how or why this selection was made. Second, IgG allotype frequencies are very different in Caucasoid and Japanese populations. Third, Graves' disease is very strongly associated with B8/DR3 in Caucasoids but with DR5 and DR8 in Japanese populations. A study of Japanese families living in America might show whether these differences are due to a different environmental factor interacting with different IgG or HLA haplotypes in the two populations or to putative susceptibility genes going with different allotypes in the two populations.

Theoretically the reasons for expecting HLA and immunoglobulin-gene linked associations with immune response in general and autoimmune disease in particular are overwhelming: HLA-DR antigens (or antigens in the same chromosome area) are necessary for antigen handling and presentation by a lymphoid cell subset; markers in this region (by analogy with the mouse) are important for interaction of T cells during a response; immunoglobulin genes are also involved in T-cell recognition and control; HLA-A,-B and -C antigens are important at the effector arm of the cellular response; and finally, C2, C4, Bf and immunoglobulin are involved at the effector arm of the humoral response. Thus, HLA and immunoglobulin genes are active throughout the immune response from recognition to control and it is slight differences in an individual allele's ability to function, or more exactly a summation of slight differences, which we are measuring as disease susceptibility. Theoretically therefore we expect that use of HLA and immunoglobulin allotyping data together with other genetic markers and environmental factors should allow autoimmune diseases to be predicted exactly. However, there is still a considerable amount of analysis of both HLA-region genes and IgG-region genes to be done in order to achieve this goal in the general population.

In Japanese families, the occurrence of Graves' disease can be exactly predicted on the basis of HLA and immunoglobulin allotypes, but it is too early to start wearing "Are you my HLA type?" badges outside Japan. Nevertheless, elimination of autoimmune diseases by genetic counselling is now much closer to being realized: if two independent susceptibility genes are necessary for disease onset, then it is possible to ensure that the genes will not occur together in the next generation.

Positronium and positronium ions

from T.C. Griffith

POSITRONS and positronium, the bound state of an electron and a positron, have in recent years been used in a rapidly increasing range of experiments in atomic physics, solid-state and surface physics and positronium chemistry. Positronium has also played an important part in fundamental experiments designed to check the validity of certain aspects of the theory of quantum electrodynamics (QED). It is therefore pertinent that the recent detection of a new entity, the positronium negative ion, Ps- (e-e+e-), initially predicted to exist as a bound state by Wheeler1 in 1946, should be greeted as an important historical landmark which could greatly extend the activities of positron physicists. The careful experiment performed by Allen Mills2 at the Bell Laboratories, New Jersey clearly demonstrates that Ps can be produced in the laboratory under controlled conditions.

Ps⁻ is the analogue of H⁻ ions produced by slow proton bombardment of thin foils and the method used by Mills incorporates the same ideas. In his experiment, a nearly monoenergetic beam of low-energy positrons, guided by a longitudinal magnetic field, strikes a thin film of carbon in ultra-high-vacuum conditions. The energy of the positrons is adjusted such that the beam is partially transmitted and application of a suitable potential to a grid located at the exit side of the carbon film will reflect the transmitted positrons back to the carbon whilst accelerating the weak beam of Ps- into a field-free drift region beyond the grid. A lithium-drifted germanium detector is used to measure the energy spectrum of the resulting annihilation photons and a y-ray peak is found whose energy depends on the accelerating potential applied to the grid. It was demonstrated that this peak can be attributed to a Doppler-shifted annihilation y resulting from the 2y decay

As well as being of interest in its own right, Ps-is also important because it might be used to produce beams of positronium of well defined energies. This could be achieved by accelerating the Ps- to a given energy and then photoionizing it to give positronium which could, perhaps, be used in scattering experiments. Another suggested application is to use the annihilation of Ps in flight to provide a tunable source of y rays of precisely known relative energy shift. The intrinsic properties of the Ps-such as its lifetime (~ 2 nanoseconds), its 2y angular correlation, its (1y/2y) branching ratio, its magnetic moment and measurement of its photoionization cross-section are obvious candidates for extensive studies.

The glamour of detecting the Ps- ions should not be allowed to overshadow the deeper significance of this experiment. The major triumph underlying this work is the dramatic technical advances associated with the production of intense beams of slow positrons of well defined energies achieved at Bell Laboratories and at Brandeis University by Karl Canter and coworkers3. Technology has now reached such a level that within a few years lowenergy positron beams of intensities of 109 positrons per second, or even several orders of magnitude higher, can be envisaged. Positron emitters created in situ in a nuclear reactor followed by carefully designed moderators and beam transport systems may be used for this purpose. If allowed to strike clean metal surfaces under ultra-high-vacuum conditions these positrons can be converted, with almost 100 per cent efficiency, into low-energy positronium atoms. We might therefore expect intense and highly localized sources of positronium atoms which can be used to study the excited states of positronium using laser beams in experiments, similar to those performed for atomic hydrogen, that will provide further high-precision tests of

Even more exotic possibilities exist. Quantum chromodynamics predict that orthopositronium can decay into a new elementary particle, the axion, and a y ray. The axion must have a mass of less than 1 MeV for this to be possible and if this were the case, then an intense positronium source from a low-energy positron beam could well find application in a search for the axion.

Two Voyagers to Saturn

The pages which follow may be taken as a celebration of the impending encounter of Voyager 2 with Saturn and are a pointer to the richness of data likely to be gathered in the next few days and weeks. Although there may be some to whom the work of these two remarkable spacecraft will be proof of how even more remarkable would have been the Grand Tour of the Solar System planned in the 1960s but executed only in the form of the two Voyagers, to most people the encounters with Jupiter and Saturn will seem exciting enough for the time being. Yet there are Uranus and Neptune to come.

This group of scientific articles includes some of the first detailed attempts to make sense of last year's Voyager 1 observations of Saturn—and Nature acknowledges its debt to Dr G. E. Hunt of University College, London for having helped to recruit these articles and to give shape to the ground they cover. The scope is necessarily restricted, for there is hardly a branch of planetary astronomy which has not been changed in some way by the data from Voyager 1—and which is not about to be changed again.

How Voyager 2 has been reprogrammed

from Edward C. Stone

In the past two years, the Pioneer 111,2 and the Voyager 13,4 encounters with Saturn have revealed a remarkable richness and diversity of physical phenomena. As a result of these discoveries and of continued Earth-based studies, major changes have been made in the observations planned for Voyager 2, providing additional opportunities for discovery and understanding of the Saturn system. These opportunities are further enhanced by the significantly different path that Voyager 2 must take through the system, passing 101,000 km above Saturn's cloud tops on 26 August as it continues on to Uranus. Of necessity, the most exciting discovery will be unexpected; but some of the opportunities for new observations are described below for each of the four major areas of investigation—the atmosphere, rings, satellites and magnetosphere.

Atmosphere

The study of the dynamics of Saturn's atmosphere is of interest because Saturn, like Jupiter, is a giant rapidly-rotating body composed mainly of hydrogen and helium, encircled by bands of clouds of frozen ammonia with large-scale wind patterns distinctly different from those of the Earth's atmosphere. On Jupiter, there are opposing eastward and westward jet streams at the edges of adjacent cloud bands, with a maximum eastward equatorial velocity of $\sim 450 \text{ km h}^{-1}$. On Saturn, Voyager 1 found equatorial winds four times faster and found that the pattern of opposing jet streams occurred only above ~35° latitude.

Voyager 2 will not only yield a monthlong time-lapse movie of the wind that the bright broad B-ring appears to consist of hundreds of ringlets separated by narrow gaps, each one of which may be cleared by small, kilometre-sized satellites. The Voyager 2 photopolarimeter will observe the star Delta Scorpii through the shadowed region of the rings for 2 h 18 min, during which time the star will

move radially outward behind the rings, its apparent intensity varying as it moves from behind a ringlet into the adjacent gap. This stellar occultation should determine the location, width and spacing

patterns, but will also provide a highresolution view of the pattern of opposing jet streams in the north polar region. The winds in the atmosphere above the clouds exhibit a different pattern which will be determined from a high-resolution thermal map of the upper atmosphere. Other studies include a deep probing of the temperature and pressure of the atmosphere by the radio beam as the spacecraft disappears behind the planet, where images of the dark side of Saturn will be taken to search for lightning. Since Voyager 1 discovered UV auroral emissions at 80° latitude and similar emissions near the equator, Voyager 2 will also perform a systematic latitude search for such emis-

Rings

The rings, the second major area of study, presented most of the surprises from Voyager 1, and the Voyager 2 observations programme has, as a result, been almost completely revised and enlarged. The Voyager 2 observations will be further improved by the increased solar illumination of the north face of the rings as the Saturn year continues towards northern summer and by a much closer approach to the rings than on Voyager 1. Unlike both Voyager 1 and Pioneer 11, Voyager 2 will view the lighted face of the rings at closest approach.

One of the Voyager 1 discoveries was

of the ringlets with a precision of 100–300 m. A second, shorter stellar occultation observation of Beta Tauri will provide five times more precise measurements of the braided F-ring and the outer edge of the main ring system. Near closest approach, the highest-resolution images should reveal any structure down to the sub-kilometre scale.

The dynamics of the braided F-ring will be studied in a sequence of observations keyed to assessing the importance of various physical processes in its formation. The fine submicrometre-sized material in the braids is radially confined by two shepherding satellites (1980 S26 and 1980 S27) on either side of the F-ring. Images of the F-ring near these two satellites may indicate whether they are perturbing the motion of the ring particles in such a way as to cause the braided appearance while repeated images of the ring should indicate whether the braided structure is stable or varies on a short time scale. Images of the portion of the ring emerging from Saturn's shadow may provide clues to the influence of electrostatic charging of the small ring particles on the braided structure, since the electrostatic charge on the particles will probably change with the cessation of photoelectron emission normally occurring in the sunlight.

The 'spokes' in the B-ring are also not understood, although they appear to form sporadically in Saturn's shadow and then almost to dissipate before the completion of a single orbit about Saturn. Like the F-ring braids, the spokes consist of fine particles, possibly elevated in a cloud above the ring plane. As Voyager 2 crosses the ring plane, three images will be taken of the rings edge-on, in search for any elevated material. Before closest approach, a 13.5-h time-lapse movie will be taken to study the dynamical properties of individual spokes as they are distorted by the greater angular velocity of the spoke material nearer Saturn.

Edward C. Stone is the Chief Scientist of the Voyager Project at the Jet Propulsion Laboratory and Professor of Physics at the California Institute of Technology, Pasadena.

Table 1 Voyager 2 closest approach distances to Saturn's satellites (23-26 August 1981)

Name	Diameter (km)	Orbital radius $(R_s)^*$	Closest approach distance (km)†
1980 S28	40×20	2.28	287,170
1980 S27	220	2.31	246,590
1980 S26	200	2.35	107,000
1980 S3	90×40	2.51	147,010
1980 S1	100×90	2.51	222,760
Mimas	390	3.08	309,990
Enceladus	500	3.95	87,140
1980 S25	30-40	4.88	284,400
Tethys	1,050	4.88	93,000
1980 S13	30-40	4.88	153,520
1980 S6	~160	6.26	318,200
Dione	1,120	6.26	502,250
Rhea	1,530	8.74	645,280
Titan	5.140	20.25	665,960
Hyperion	290	24.6	470,840
lapetus	1.140	59	909,070
Phoebe	~160	215	2,075,640

- * Mean distance of the satellite from the centre of Saturn in units of Saturn radii (1 $R_s = 60,330$ km).
- † From a distance of 100,000 km, the geometrical resolution of the imaging system is 2 km per line pair.

The closer approach to the rings also makes possible further study of the electrostatic discharges detected by Voyager 1. Although the origin of the discharges has not been directly determined, they occur episodically every 10 h 10 min, suggesting an association with a satellite with this orbital period embedded within the B-ring. Additional high time-resolution samples of electromagnetic wave activity will be acquired over the 10-40-MHz frequency range, including one when the spacecraft crosses the ring plane.

Satellites

Another major area of study is the saturnian satellites, of which 17 are now known. Of these, only Titan is a major satellite, similar in size to the planet Mercury. Titan, with a dense atmosphere which includes nitrogen and methane in which organic photochemistry is occurring, was a primary target for Voyager 1. Voyager 2 will observe Titan from a much greater distance (see Table 1), returning information on the light-scattering properties of the photochemical haze and possibly on the winds.

Seven of the satellites are intermediate in size, composed mainly of water ice, with diameters ranging from about 300 to 1,500 km. Of these, Voyager 1 observed Mimas, Dione and Rhea with high enough resolution to show that their icy surfaces are heavily cratered from impacts, as was expected. Unexpected, however, were regional systems of fractures and sparsely cratered plains which are evidence of significant crustal evolution. Voyager 2 will extend the high-resolution coverage to Tethys, which has a ~750-km-long valley, and to Enceladus, which is highly reflective and appears to be relatively devoid of impact craters. The absence of craters on Enceladus would require a source of energy large enough to cause significant modification of the surface. To investigate Enceladus's thermal properties, the rate of cooling of the satellite as it moves into Saturn's shadow will be

determined from IR temperature measurements.

The second secon

Less is known about Hyperion and Iapetus, the other two intermediate satellites. Voyager 2 will fly closer to both than did Voyager 1, returning images with enough resolution to determine whether there are large valleys as on Tethys or whether there is any other evidence of crustal evolution.

As indicated in Table 1, there are at least nine other smaller satellites with estimated diameters ranging from about 30 to 220 km. Voyager 1 determined approximate shapes for only 1980 S28, which is just outside the main rings, and the two satellites, 1980 S1 and 1980 S3, which share essentially a common orbit. All three were found to be distinctly nonspherical. Voyager 2 will determine the shape of all the remaining known satellites, including the F-ring shepherding satellites (1980 S26 and 1980 S27), the two satellites recently discovered in ground-based images⁵⁻⁷ which share a which share a common orbit with Tethys (1980 S13 and 1980 S25) and 1980 S6, which shares an orbit with Dione. There will also be a search for new satellites, both outside and embedded within the ring system. Photometrically accurate measurements of the amount and degree of polarization of light scattered from the different satellites will provide additional information on the texture and gross composition of their surfaces.

Plasma

The fourth major area of study is that of the planetary magnetic field, plasma, trapped energetic particles and wave emissions comprising Saturn's magnetosphere. Periodic bursts of radio emissions in the 100-500-KHz frequency range provided the first accurate determination of the period of rotation of Saturn's magnetic field, which is believed to be the period of rotation of Saturn's interior regions where the magnetic field originates. This period, which is 10 h 39.4 min, will be more accurately determined with the longer time-base provided by Voyager 2, while measurements of Saturn's magnetic field may identify the longitudinal asymmetry resulting in the localization of the radio emission to specific saturnian longitudes. Voyager 2 will also provide additional observations of the 2.7-day modulation of the radio emissions thought possibly to result from Dione's interaction with the magnetosphere.

The effects of Mimas and Enceladus on the magnetosphere will be directly measured as Voyager 2 passes just inside Mimas's orbit. Measurements deep within the magnetosphere will better define the structure of the equatorial disk of plasma and the extent to which the icy satellites are sources or absorbers of magnetospheric particles. From Voyager 1, it is known that Titan's atmosphere is the source of at least some of the particles.

Voyager 2 may also provide a rare opportunity for observing the effects of Jupiter's magnetotail on Saturn's magnetosphere. There is recent evidence from Voyager 2 that Jupiter's magnetotail, which may resemble a tattered wind sock flapping in the solar wind, extends at least 4.5×10^8 km outwards from Jupiter. Because, during the past few months, Saturn has been almost radially aligned with Jupiter, it is likely that Saturn has been occasionally immersed in the extended jovian magnetotail. Such an immersion could at least temporarily result in variations in the size, shape and other characteristics of Saturn's magnetosphere, leading to the possibility that there are significant differences between the Voyager 2 observations and those of Pioneer 11 and Voyager 1.

Outcome

Intensive observations of the saturnian system, which began on 5 June, will continue until 28 September, when Voyager 2 will return to the cruise mode and, like Voyager 1, continue exploring the interplanetary medium at increasing distances from the Sun. In late 1985, Voyager 2 will return to the encounter mode as it approaches a flyby of Uranus on 24 January 1986, and heads towards an encounter with Neptune on 24 August 1989. Beyond Neptune, both spacecraft will continue exploring the outer limits of the region dominated by the solar wind, where low-energy galactic cosmic rays may be first observed and beyond which lies the interstellar medium. Thus, there is potential for a continued and significant scientific return from the Voyager spacecraft well beyond that originally planned for the mission to Jupiter and Saturn.

Thermal structure and dynamics of Saturn and Jupiter

J. A. Pirraglia⁺, B. J. Conrath⁺, M. D. Allison[†] & P. J. Gierasch[‡]

* NASA/Goddard Space Flight Center, Code 693.2, Greenbelt, Maryland 20771, USA
† Department of Space Physics and Astronomy, Rice University, Houston, Texas 7701, USA
‡ Laboratory for Planetary Studies, Cornell University, Ithaca, New York 14853, USA

High resolution Voyager IRIS measurements for Saturn and Jupiter are assembled in meridional cross-sections of the retrieved upper tropospheric temperatures. The calculated thermal wind shear in the upper troposphere is highly correlated on both planets with the cloud top winds derived from imaging data. In contrast, temperatures below ~ 300 mbar are not simply related to the zonal jet structure. The upper tropospheric temperatures seem to have been more consistently correlated with cloud top winds than with major albedo features at the time of the Voyager encounters.

THE atmospheres of Saturn and Jupiter are the most energetic observed in the Solar System. Both planets are encircled by high velocity super-rotating equatorial currents and an attendant system of axially-symmetric westward and eastward jet streams at higher latitudes. While differing in their axial tilt, gravitational potential, emission temperature and visual contrast, Saturn and Jupiter are approximately similar in size, rotational period, and gross composition. Despite these similarities major differences in their dynamical structures are observed. Smith et al. report that the equatorial prograde velocities measured relative to the radio period are much larger and wider in latitudinal extent on Saturn than on Jupiter. Also, with one exception, anticyclonic shear on Jupiter is generally well correlated with brighter cloud bands or zones while on Saturn no such correlation is evident.

A preliminary analysis² of the saturnian atmosphere by the Voyager IR instrument (IRIS)³ has revealed substantial latitudinal structure in upper tropospheric temperatures. This structure is further investigated here by constructing a meridional temperature cross-section and, for comparison, similar cross-sections were obtained using IRIS data for Jupiter. Correlation of the structure of the upper troposphere with the cloud level dynamics is explored for both planets by comparing the computed thermal wind shear with the imaging measurements of zonal wind velocites.

Zonal thermal cross-sections

A meridional thermal cross-section for Saturn's northern hemisphere is shown in Fig. 1a: temperature profiles retrieved between 730 and 150 mbar from 82 individual spectra taken with roughly uniform distribution in latitude but at various longitudes were assembled. For these measurements the IRIS field of view projected onto the planet varied between 2° and 5° in latitude. The vertical resolution for the retrieved temperature is $\sim \pm 0.5$ scale heights and the error in temperature due to instrumental noise for each spectral measurement is $\sim \pm 0.5$ K. Continuous high resolution latitudinal coverage was available only in the northern hemisphere.

Thermal cross-sections between 140 and 500 mbar for Jupiter's northern and southern hemispheres, assembled from 150 and 166 Voyager 1 spectral measurements respectively, are shown in Fig. 1 b, c. The field of view projected onto the planet, vertical resolution, and thermal noise level for these data are comparable with those for Saturn.

The pointing data for these measurements were provided by the Voyager supplementary experimenter data record (SEDR)⁴. In some cases it has been possible to check this pointing information with reference to simultaneously shuttered Voyager imaging records. In these cases agreement between the imaging and the SEDR has been within 1° latitude. Although such verification is impossible for spectral measurements taken on the dark sides of the planets, the estimated residual 3σ pointing error is expected to be within 1°-3° of latitude, depending on the projection of the field of view onto the planets. Latitudinal correlations between the thermal and visual observations may therefore be sought within these error bounds.

The gross structures exhibited in the cross-sections for both Saturn and Jupiter show horizontal scales of variation comparable with the width of the zonal jet streams at mid-to-high-latitudes. The direct visual comparison of latitudinal thermal variation in these cross-sections with both albedo and wind velocity is more difficult. The Saturn cross-section (Fig. 1α) shows no simple correlation with the visual albedo variation measured by Voyager imaging¹, but some correlation is observed between the visual albedo and the structure of Fig. 1 b, c for Jupiter at upper levels near 150 mbar. Higher albedo is in most places associated with lower temperatures.

The upper tropospheric structure for Jupiter seems to be in rough agreement with the IR measurements of Pioneer 11 reported by Orton et al.⁵. A region of special interest is that

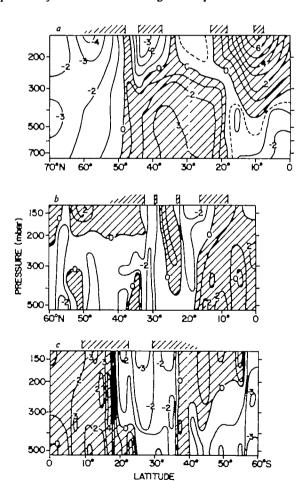

Fig. 1 Zonal cross section of deviations from the latitudinal mean retrieved temperature (K) in. a, Saturn's northern hemisphere as measured by Voyager 1 IRIS, November 1980. b, Jupiter's northern hemisphere, measured in March 1979. c, Jupiter's southern hemisphere, measured in March 1979. The latitudes of major albedo features are indicated schematically.

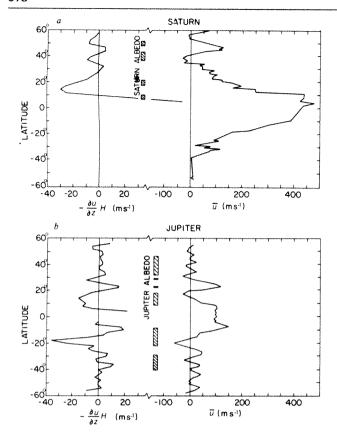

Fig. 2 a, Comparison between the thermal wind shear at 150 mbar and the cloud top zonal wind velocities on Saturn. b, Comparison between the thermal wind shear at 140 mbar and the cloud top zonal wind velocities on Jupiter obtained from Voyager 1 IRIS measurements. For convenience the negative of the wind shear multiplied by one atmospheric scale height is displayed. The major albede contrast is also indicated.

between 24° and 30° N (historically the North Temperate Belt or NTB). According to Peek⁶ this region is one of the most variable on the planet. The region was dark during the Pioneer 10 and 11 encounters and the 20 µm (upper tropospheric) temperatures were correspondingly high. Figure 1b shows that this region was still warm at 150 mbar during the Voyager 1 encounter; it was also warm during the Voyager 2 observations. The appearance of this region during the Voyager encounters, however, showed a high albedo typical of a zone¹. According to the Earth-based observations by R. F. Beebe (personal communication) the belt-like region began to cloud over in 1977-78 so that the zone-like appearance had been present for <2 yrs before the Voyager encounters. This interval is, however, well within the radiative response time of 10⁸ s for this level of Jupiter's atmosphere⁷, and the upper tropospheric temperatures may not vet have responded to the reduction of IR flux at the cloud level.

The thermal cross-sections for both planets show substantial differences in the horizontal structure between levels above and below 300 mbar. These differences may reflect inaccuracies in the temperature retrievals at low levels due to the opacity effects of latitudinally variable aerosol concentrations. If the retrieved temperatures are correct at all levels, however, then the presence of some as yet unknown driving mechanism is indicated. Possible candidates include aerosol heating in the upper troposphere, radiative screening effects associated with clouds, adiabatic heating and cooling due to vertical motion⁸, and eddy or wave generated fluxes of heat and momentum.

Thermal wind shears

The observed latitudinal gradients in temperature on Saturn and Jupiter require a dynamical response, and the velocity and length scales inferred from the Voyager imaging measurements are consistent with geostrophic balance. Therefore, with the additional assumption of hydrostatic equilibrium, the vertical

shear of the eastward zonal flow u is given by the thermal wind equation

$$\frac{\partial u}{\partial z} = -\frac{R}{2\Omega a H \sin \lambda} \frac{\partial T}{\partial \lambda}$$

where the derivative of temperature with respect to latitude λ is taken along an isobaric surface, and R is the gas constant. The planetary rotational frequency is $\Omega=1.64\times10^{-4}~\rm s^{-1}$ and $1.76\times10^{-4}~\rm s^{-1}$ for Saturn and Jupiter respectively. The respective planetary radii are given by $a=6.03\times10^4~\rm km$ and $7.14\times10^4~\rm km$. The scale height H is $\sim38~\rm km$ for Saturn and 22 km for Jupiter at upper tropospheric levels. Because of the limited spatial resolution of the IR measurements and the uncertainty in the ammonia condensation level, it is impossible to match reliably an integrated wind shear to the zonal velocities at the cloud deck. Nevertheless, an estimate of the thermal wind shear in the upper troposphere for the observed zonal temperatures on the two planets is of diagnostic value in determining the extent of the coupling between the upper level dynamics and the observed zonal winds.

Figure 2 shows the thermal wind shear derived from the temperature retrievals at 150 mbar for Saturn and 140 mbar for Jupiter. These computations used the same data sets as those used for the cross-sections in Fig. 1. For Saturn the meridional derivative was computed for every 2.5° latitude as a finite difference over 5° between temperatures given by a smooth fit to the data. For Jupiter the finite difference interval was 4° at every 2° of latitude. The imaging measurements of the zonal velocity \bar{u} at the cloud tops are plotted to the right of the wind shears for comparison. The cloud top zonal winds for Saturn were taken from ref. 1 while those for Jupiter were adapted from ref. 9. The approximate latitudinal positions of the visual albedo variations at the cloud deck are also indicated in Fig. 2 with dark markings for 'belts', interspersed with the lighter 'zones'.

Wherever the sign of $-(\partial u/\partial z)H$ is the same as that for \bar{u} a reduction of the cloud top velocity with height is implied. Different scales have been used for $-(\partial u/\partial z)H$ and \bar{u} to aid their visual comparison. Because of the finite field of view for the measurements computed shear magnitudes are best regarded as lower limits for gradients of thermal fields which may vary significantly over scales too small to be completely resolved.

A comparison of the results for the two planets implies that the dynamical length scale, as indicated by the latitudinal change in the sign of the shear, is slightly larger for Saturn than for Jupiter. In general, there is a good correlation between the positions of most of the observed jets and the wind shear extrema. The shear is in the sense required to reduce the strength of the zonal velocities at cloud level with height, but the magnitude of the shear is such that several scale heights would be required for a significant modification of wind speeds comparable with those observed at the cloud tops.

On Jupiter, alignment between the peaks of the jets and extrema of the thermal wind shear is in most places within the $\pm 1-3^{\circ}$ of residual pointing uncertainty. The agreement seems to be especially good at the strong prograde jet at 23° N and throughout the alternating system of jets between 15 and 40° S. Although it is not certain how close to the equator the computed thermal wind shears are valid, they have been plotted within $\pm 4^{\circ}$ of the equator and some reduction in the strength of the equatorial jet with height is indicated.

The thermal wind shear at 18° S on Jupiter seems to be stronger than at any other mid-to high-latitude location. The retrograde jet at 20° S as measured by the Voyager imaging is unusually broad. The apparent enhancement in the wind shear at this location may therefore simply reflect the better spatial resolution in the thermal measurement relative to the jet width.

Note that the region between 24 and 30°N on Jupiter retains a strong correlation between the thermal wind shear and the wind field at the cloud tops. This is a consequence of the relatively warm upper troposphere even through this normally belt-like region had clouded over before the Voyager 1 encounter. Thus, the upper tropospheric temperatures seem to have been more

strongly correlated with the cloud level jets than with the large scale albedo features at the time of the Voyager observations.

The computed thermal wind shear for Saturn is closely correlated in position with the retrograde jet centred near 38° N and with the prograde jet near 46° N, again in the sense required to reduce the cloud top velocities with height. The magnitude of the thermal wind shear relative to the measured \bar{u} , however, is much larger for the retrograde jet. There is also some correlation between the vertical shear and the weak retrograde jet centred near 55° and at least a correlation in sign for the prograde cloud motions around 32° N. The thermal wind shear between 5° and 10° N indicates some reduction in the strength of the very rapid equatorial jet with height. Between 10 and 30° N the computed thermal wind shear shows a significant departure from the general correlation observed elsewhere. Here the shear is in the sense consistent with a retrograde velocity, but the imaging measurements show this region to be a part of the prograde equatorial jet.

Smith et al. indicate that the Saturn jets at latitudes above 35° show some correlation with the albedo variation. Unlike Jupiter, however, the peaks of the jets seem to coincide with the middle of the bright and dark bands. It is interesting that the extrema of the computed thermal wind shear also show some correlation with the middle of the bright and dark bands, not only at the same high latitudes, but also at 32° N and especially at 15° N where the strong retrograde shear corresponds closely to the middle of a bright region to the south of Saturn's north equatorial belt. Comparison of thermal wind shears with zonal velocities in Saturn's southern hemisphere must await the more

comprehensive Voyager 2 IR measurements.

Conclusions

The thermal wind shear calculated from the IRIS derived temperatures in the upper troposphere is highly correlated with the imaging derived jets at most latitudes on both Jupiter and Saturn and is in the sense required for the wind to decrease with height. An exception is the strong retrograde feature inferred from the thermal data at 15° N on Saturn which does not appear in the imaging data. Contrary to expectation, the thermal structure in the lower troposphere below ~300 mbar is not well correlated with cloud top winds on either planet. This may be the result of a haze or cloud effect not taken into account in the thermal retrievals; however, the possibility that the thermal structure is real cannot be ruled out until particulate contributions to the IR opacity of the lower tropospheres of both planets is better understood.

The thermal wind shear and major albedo features have similar latitudinal scales, but the exact nature of this correlation differs on the two planets. On Saturn, the extrema in the wind shear tend to fall near the centres of the bands while on Jupiter they occur near the interfaces of belts and zones. The observation of the anomalously bright but warm region between 24° and 30° N on Jupiter suggests a better correlation between upper tropospheric temperatures and the jet streams than with the large scale albedo features at the time of the Voyager encounters.

We thank Rudolf Hanel, principal investigator for the Voyager IRIS team, for valuable comments and suggestions.

Morphology of Saturn's aurora

B. R. Sandel & A. L. Broadfoot

Earth and Space Sciences Institute, University of Southern California, Tucson Laboratories, Tucson, Arizona 85713, USA

Aurorally-excited emissions of atomic and molecular hydrogen come from a narrow circumpolar band near 80° north and south latitude on Saturn. The aurorae, which lie near the edge of the polar cap region, are continuously excited in both the north and south. If the strong variations observed in the auroral intensity are temporal, rather than longitudinal, they may be related to the periodic structure in the Saturn kilometric radiation.

BECAUSE Saturn possesses a dense atmosphere and a strong magnetic field, it is reasonable to expect that aurorae should also be present. Before the encounter of Voyager 1, two lines of evidence suggested the presence of polar aurora on Saturn, but both admitted alternate interpretations. Pioneer 11's ultraviolet photometer showed enhanced emission in its long wavelength channel when the field of view crossed the polar limbs, as compared with the centre of the disk1; this could have been due to auroral excitation or to limb brightening. Spatially-resolved images of Saturn obtained by the International Ultraviolet Explorer (IUE) satellite showed enhancements in $HLy\alpha$ emission which could have come from Saturn's polar atmosphere². At different times the enhancements appeared at both north and south poles, but were sometimes completely absent. The polar enhancement ranged from 300 to 900 R averaged over the resolution element of 6×10 arcs. The source of the emission could not be localized to the atmosphere of Saturn, and it was noted that the observations were consistent with scattering of sunlight by a sporadic cloud of neutral hydrogen associated with Saturn's rings. The first unambiguous evidence for saturnian aurora was provided by the UV spectrometer (UVS) on board

Voyager 1. Aurorally excited emissions were found at HLyα and in the Lyman and Werner bands of H₂ near Saturn's poles. We now expand that brief description³ of the aurora.

The UVS is an objective grating spectrometer covering the wavelength range 530-1,700 Å in 126 contiguous channels^{4,5}. This wavelength region includes the atomic HLy α line that can be excited by resonance scattering or particle impact, and the particle-excited Lyman and Werner bands of molecular hydrogen. During the encounter the UVS was used to map the planet at varying spatial resolutions.

Of the data examined so far, the polar scan sequence shown in Fig. 1 has yielded the best information on the position of the aurora. The path of the slit intersected an auroral oval twice, once on each side of the pole. The presence of the aurora was defined by locally enhanced emissions at HLya and in the H2 bands. In the polar cap region, the auroral emission was reduced by a factor of at least 4, and may have been entirely absent. To determine the width and location of the auroral excitation, the data from the crossing on the near side of the pole have been compared with a simple model of the distribution of auroral emission. This model shows that the auroral emission extends

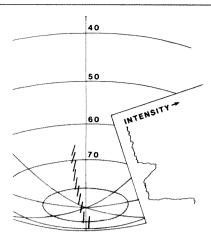

Fig. 1 Geometry of a polar auroral scan. The range is $3.6 R_s$ and the latitude of the spacecraft is -36.6°. Dashes show the position of the 0.1° × 0.86° UVS slit at 1.5-min intervals as the slit scanned across the south pole and onto the dark limb. The stippled area shows the inferred location of the source of auroral emission between 78° S and 81.5° S. The slit crossed the aurora on the near side of the pole at $\lambda_{SLS} = 190^{\circ}$ near the dusk terminator. H₂ band emission along the path of the slit is shown in the inset.

between 78 and 81.5° S. On the far side of the pole, the emission occurs very close to the limb of the planet, and is difficult to locate accurately. Furthermore, on the far side, the uncertainty in latitude introduced by parallax and the uncertain altitude of the auroral emission is much greater. No information on the distribution of the intensity within the aurora is yet available. The average apparent brightnes is ~5 kR based on the intensity of the 1,105-Å H₂ band feature, which should be optically thin⁵. Because the aurora was observed at an angle of 56° from the local zenith, the nadir intensity was $\sim 2.8 \, kR$. Figure 1 shows the auroral oval at constant latitude; this is consistent with, but not required by, the data. We have also anticipated a result derived later—that the aurora is at least roughly continuous in longitude, to extend the auroral oval around the planet in longitude.

In the north, the aurora occurs at nearly the same location, as the nearly dipolar, axisymmetric nature of the magnetic field would imply. Approximately 11 h after closest approach the north polar area was searched for aurora. The geometry was similar to that shown in Fig. 2b, except that the spatial resolution was a factor of 3 better. Two scans near local midnight show that the boreal aurora lies poleward of 76° N, and may not extend below 78° N. These scans do not define the poleward extent of the excitation. We assume that the boreal and austral aurora have the same latitudinal extent, as their equatorward boundaries fall at nearly the same latitude, and the magnetic field has north-south symmetry. The two scans show a 50% increase in H₂ band emission (from 2.5 to 3.7 kR) from the first to the second, 20 min later. As the planet rotated only 13° in this time. and because the field of view was positioned near the 'elongation' of the auroral oval, the longitude range within the slit did not change significantly between scans. The change in measured intensity is probably due to a temporal variation in auroral brightness.

More extensive observations at lower spatial resolution are available for study. The north-south map (NSM) sequence was executed ~36 h before and after closest approach. This observing sequence, shown in Fig. 2, consisted of a series of swaths from north pole to south pole, approximately along the central meridian of the planet. Each swath of the pre-encounter NSM was made up of 12 steps in latitude, each step lasting 48 s. Swaths were repeated at intervals of 12 min, or 7° in rotation phase, during an almost complete rotation period of the planet. Saturn was therefore mapped in latitude (by stepping the scan platform) and in longitude (by taking advantage of the planet's rotation).

The NSM sequences show that aurorae are present near both poles, and that they are probably continuous, at least during the

few days nearest encounter. Because the apparent size of the auroral oval is small, the fact that the slit does not always scan exactly along the central meridian is important. The field of view was well centred on the central meridian at the beginning of the post-encounter NSM, but drifted partially off the aurora to the east during the 10-h sequence. Therefore we cannot derive strong conclusions about time or longitudinal variations over the full span of the observation, but the data clearly demonstrate the presence of aurora near the north pole throughout the NSM sequence. The favourable configuration shown in Fig. 2b was maintained for the first 3 h of the sequence. During this time the brightness of the H₂ bands decreased from its initial level of 20 kR by a factor of ~2. This change can be interpreted as a temporal variation or as a longitudinal variation in the brightness of the aurora. The field of view sampled the auroral oval on both sides of the pole, so the presence of a brighter area near both $\lambda_{SLS} = 25^{\circ}$ and 200° is compatible with the data. (The longitude system used here, λ_{SLS} , is based on a sidereal period of 10 h 39.4 min defined by the Voyager planetary radio astronomy experiment⁷.)

A similar well-defined variation was recorded during the pre-encounter NSM. Part of the data for which we can rule out significant changes in signal level induced by changes in the position of the field of view are shown in Fig. 3. The H₂ band intensity increased by a factor of 5, remained high for 2 h (or \sim 70° in Saturn rotation phase) then returned to its lower level. At earlier and later times, the signal was about the same as the lower level shown in Fig. 3, but at these times the signal could have been modulated to some extent by changes in the position of the field of view. Note that the longitude of the field of view was $\sim 160^{\circ}$ at the peak in H₂ band emission. This differs from the position quoted earlier³ because we have now included the fact

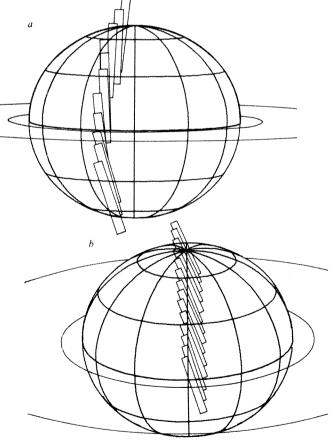

Fig. 2 Views from the spacecraft showing the geometry of the North-South Map sequence. The pre-encounter NSM a was executed when the latitude of the spacecraft was 4.8° N. Both boreal and austral aurorae were visible, although the austral aurora was quite near the limb of the planet. Near the poles, the slit was near 10.00-11.00 LT. For the post-encounter NSM b, the latitude of the spacecraft was 22° N and the latitude of the austral aurora was not included in the scan. The rectangles show the positions of the UVS slit

during a typical swath. Saturn's central meridian is near 3.00 LT.

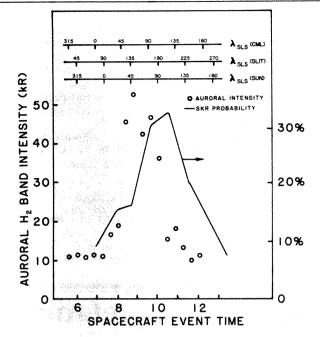

Fig. 3 H_2 band intensity as a function of time during a portion of the pre-encounter NSM. The intensity integrated over the Lyman and Werner bands of H_2 has been determined from the measured intensity of the 1,105 Å feature, which is relatively unaffected by self-absorption. The solid line shows the probability for detection of Saturn kilometric-wave radiation⁸.

that the field of view is not on the central meridian. At the same time, the austral aurora showed a qualitatively similar variation. The unfavourable observing geometry (see Fig. 2b) precludes a quantitative analysis of the austral auroral intensity based on the NSM data. Figure 3 also shows the probability of occurrence of the Saturn kilometric radiation (SKR) taken from Gurnett et al.8. Following the discovery of the SKR by Kaiser et al.9, the probability of observing this radiation was found to be strongly correlated with the longitude of the Sun in the λ_{SLS} system⁸ For the comparison in Fig. 3, the longitude of the Sun was calculated as a function of spacecraft time, and then the relationship between SKR probability and solar longitude was used to plot the SKR probability on the same time scale as the auroral brightness. In spite of a phase difference of $\sim 50^{\circ}$, the correlation between the SKR probability and the auroral intensity apparent in Fig. 3 is good enough to suggest that the two phenomena may be closely linked. A test of this correlation must await the Voyager 2 encounter.

Spectra of the aurora are compared in Fig. 4. The signature of the H_2 Lyman and Werner bands is present between ~ 900 Å and 1,130 Å. The latitude of the spacecraft was different when the two spectra of Saturn's aurora were taken, implying different pathlengths through the atmosphere to the auroral source. Stronger self-absorption by H_2 in the longer atmospheric pathlength of the middle spectrum probably accounts for the gross differences shortward of 1,050 Å in the Saturn spectra (see Fig. 9 of ref. 5). The differences between the auroral spectra of Saturn and Jupiter between 1,100 and 1,200 Å parallel those in the dayglow spectra of the two planets³.

The power required to drive the aurora was estimated earlier³ to be $\sim 2 \times 10^{11}$ W. This was based on an average brightness of 5 kR in the H_2 bands extending over an area of 4.6×10^{18} cm² (the surface area of Saturn between 78° and 81.5° latitude) and the efficiency for electron excitation of the H_2 bands⁵. This re-analysis shows no basis for altering the early estimate, but it does emphasize that the presence of temporal and/or longitudinal variations in the surface brightness of the aurora may bias the apparent average brightness. About two thirds of the auroral information available from the Voyager 1 encounter has been extracted.

Other sources of uncertainty are important. The brightness over all wavelengths in the H_2 Lyman and Werner band systems has been estimated using the measured intensity of the 1,105 Å

feature. This feature is relatively unaffected by self-absorption in long slant-paths through the atmosphere to the auroral source and hence more likely to represent the true emission intensity. The uncertainty in the model relating the total H₂ band emission to the 1,105 Å feature may be as much as a factor of 2 (D. E. Shemansky, personal communication). Further uncertainty is introduced when the apparent brightness of an aurora near the limb of the planet must be used to calculate the surface brightness. Hence we have given more weight to the intensity measurements made at the smallest atmospheric pathlengths in assigning the average auroral brightness of 5 kR. Because of these uncertainties, figures such as auroral power dissipation are uncertain by a factor of at least 4. On the other hand, the relative brightness measured within a given sequence (for which the observing geometry remains constant) depends mainly on the pointing accuracy and should be very good. The location of the aurora, at least at the time of the observation in Fig. 1, is well defined to within at most 2° in latitude. Finally, the emissions in the H_2 bands and at $HLy\alpha$ from a thin layer above the sub-solar limb of Saturn³ are too weak to contaminate these auroral measurements significantly.

The aurora described here are probably related to the bursts of $HLy\alpha$ emission reported by Clarke et al.². The $HLy\alpha$ component of the auroral emissions is generally a factor of ~ 5 fainter than the H_2 band emission. The brightest $HLy\alpha$ emission measured in the UVS data was 9 kR observed during the pre-encounter NSM. Assuming that the radiation reported by Clarke et al. arose from either the northern or the southern aurora defined by the UVS, we estimate that the true surface brightness corresponding to the bursts reported by Clarke et al. ranges between 13 and 40 kR. The brightest levels were observed in only one of the seven observing periods distributed over 6 months; their lowest level bursts detected correspond roughly in intensity to the brightest $HLy\alpha$ emission measured to date by Voyager.

The morphology of Saturn's aurorae resembles that of Earth's aurorae more than that of Jupiter's aurorae. The edge of Saturn's polar cap region lies at a latitude of 78.7°-75° (ref. 6), and thus corresponds closely to the location of the auroral excitation, as in the case of the Earth. This suggests that analogous mechanisms supply energy for the aurora on the two

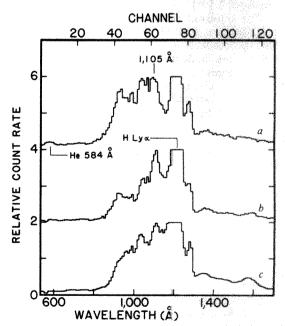

Fig. 4 Auroral spectra. a, Saturn aurora, observed at a local zenith angle 60°. b, Saturn aurora, local zenith angle 76°. c, Jupiter aurora. Aurorally-excited emissions in the Lyman and Werner bands of H₂ are apparent between 900 and 1,130 Å. The spectra have been normalized to equal levels at 1,105 Å. The Saturn spectra differ markedly between 850 Å and 1,050 Å because of different absorption pathlengths. The 1,105 Å feature marked was used as an indicator of the intensity radiated in the H₂ bands. The HLyα line has been truncated.

planets. On the other hand, the equatorward boundary of Jupiter's aurorae matches the magnetic projection of Io's plasma torus onto the atmosphere, suggesting excitation by an interaction between the atmosphere and the plasma torus11. (Aurorae may be present nearer the poles, at the boundaries of the polar caps, as well.) The energy deposited in the Earth's atmosphere by aurorae is correlated with geomagnetic activity, ranging over more than 2 orders of magnitude¹². The average value¹³ is probably near 1.7 erg cm⁻² s⁻¹, which corresponds to about 3×10^{10} W, roughly 1/7 of the power deposited at Saturn. The interaction between the magnetosphere of a planet and the solar wind, the ultimate source of auroral energy on Earth and probably on Saturn, is important in determining the power available to auroral processes. This interaction transfers about

 10^{11} W into Earth's magnetosphere 14 , about 1/10 of the 10^{12} W injected into the saturnian magnetosphere, calculated using measurements of the saturnian magnetic field⁶ and general scaling relationships for magnetospheric parameters 14. Thus the ratio of power in aurora on the two planets is about the same as the ratio of the power transferred to the magnetosphere from the solar wind. This, and the occurrence of aurora near the edges of the polar caps on both planets, suggest that the aurorae result from similar magnetospheric processes.

Saturn ionosphere: theoretical interpretation

S. K. Atreva* & J. H. Waite Jr

* Department of Atmospheric and Oceanic Science, Space Physics Research Laboratory, The University of Michigan, Ann Arbor, Michigan 48109, USA; † Marshall Space Flight Center, Huntsville, Alabama 35812, USA

Voyager 1 high latitude and Pioneer 11 equatorial ionospheric structure indicate a solar EUV-controlled ionosphere with a possible molecular ion in the topside. Vibrationally excited H_2 in the high latitudes may be an important loss mechanism. Dynamical effects are expected to be important for determining the peak density and its location.

THE Voyager 1 coherent dual-frequency radio system (RSS) at wavelengths 3.6 and 13 cm provided the first look at a high latitude (~73 °S) ionospheric profile on Saturn¹. The entry data reveal that near the evening terminator (solar zenith angle, $\xi = 89^{\circ}$), the peak electron density of 2.3×10^{4} electrons cm⁻ occurred at a height of ~2,500 km from the 1 bar pressure level. Earlier observations on Pioneer Saturn measured a peak electron density of 1.1×10^4 cm⁻³ at 1,800 km in the 10 °S latitude range². The observed ionospheric characteristics point to a markedly different ionosphere from that expected on conventional theoretical grounds.

The RSS ionospheric measurements were accompanied by a simultaneous measurement of the neutral atmosphere by means of the Voyager UV spectrometer (UVS). Modelling studies suggest that the observed ionosphere is controlled principally by the ionization of the neutrals caused by the solar EUV.

The UVS solar occultation measurements yield a neutral exospheric temperature of $820 \pm 100 \text{ K}$ at 62,000 km (ref. 3). The large size of the Sun (~500 km) projected on Saturn means that the height level at which the temperature reaches its exospheric value cannot be determined accurately. The exospheric temperature, however, is nearly the same as the topside plasma temperature (750 K)¹.

Preliminary analysis of the UVS stellar occultation data indicates that the temperature is essentially isothermal (~150-200 K) in the mesosphere up to $\sim 750 \text{ km} (H_2 \simeq 5 \times 10^{13} \text{ cm}^{-3})$ and an average temperature gradient of ~0.55 K km⁻¹ prevails above this altitude resulting in an exospheric temperature of -825 K at 2,000 km above the 1-bar pressure level. Indeed, the Saturn stellar occultation transmission characteristics are similar to those of the Jupiter stellar occultation data collected on Voyager 2 (refs 4, 5) when the height scale is corrected for the lower acceleration due to gravity on Saturn. With this information and the hydrostatic law, a working model of the atmospheric density profile at the ionospheric heights can be constructed. An important caveat is that the Voyager ionosphere was measured at high latitudes, while the neutral atmosphere used here is essentially from equatorial to mid-latitude measurements³. The auroral activity on Saturn, however, is confined to the latitude band 78°-81.5 °S which is well outside the latitude region (73 °S) of the ionospheric measurements discussed here. Therefore, no substantial change is expected in the neutral atmosphere at the ionospheric heights from the low to the high latitudes on Saturn.

Knowledge of the atmospheric mixing as represented by the eddy diffusion coefficient, K, is important for determining the distribution of the hydrocarbons which act as an important sink to the major ions, H^+ , H_2^+ and H_3^+ (refs 6, 7). K_h at the homopause may be determined from the atomic hydrogen abundance deduced from the planetary Ly α intensity^{4,8,9}. The UVS data yield 3.3 kR for Saturn Lyα dayglow³ implying 5× $10^{16} \, \mathrm{cm^{-2}} \, \mathrm{H}$ atoms above the homopause, and consequently K_{h} of $(1.5-5.0) \times 10^5$ cm² s⁻¹.

The hydrocarbon density distributions were calculated considering CH4 photolysis with the eddy diffusion coefficient varying inversely as the square root of the atmospheric number density⁷

The important chemical reactions for the Saturn ionosphere were taken from previous work^{6,10}. We consider here lowpressure, low plasma temperature (T_e) approximation for the radiative recombination reaction rate of the major topside ion, H⁺; the new rate is $4 \times 10^{-12} (250/T_e)^{0.7} \text{ cm}^3 \text{ s}^{-1}$ (ref. 11). The calculated ionospheric profile with a comparison with the Pioneer equatorial¹² and Voyager high latitude¹ data are shown in Fig. 1. Protons (H⁺) comprise the major ions in altitudes >750 km. Below 750 km, a transition to H₃⁺ and heavy hydrocarbon ions such as C₂H₅⁺ and CH₅⁺ occurs. Conversion to the higher order hydrocarbon ions, C₃H₅⁺ and C₄H₅⁺, is also probable in the lower ionosphere8.

Although the Pioneer and Voyager data differ in details, there is general agreement about the location and magnitude of the peak, and the extent of the ionosphere. The observed peak electron density in the Voyager data is about a factor of 10 lower than the calculated one. A similar low density jovian ionosphere profile measured by Voyager 1 was interpreted as being due to the reaction of H⁺ with vibrationally excited H₂ (ref. 10). The

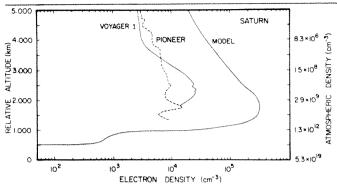

Fig. 1 Model calculations and observations of the Saturn ionosphere. The Pioneer data refer to low latitude (~10 °S), while the Voyager data are for the high latitude (~73 °S)

relatively low exospheric temperature (~800 K) on Saturn results in a small population of H_2 in $v' \ge 4$ vibrational state so that the charge exchange reaction between H⁺ and H₂ $(v' \ge 4)$ would not be expected to be as important on Saturn as on Jupiter. However, the H₂ vibrational levels may be non-thermally populated due to electron precipitation processes. Such non-thermal vibrational distributions were suggested by Cravens¹³ from modelling of jovian electron precipitation processes. Such processes could be important in interpreting the Voyager/Saturn data provided that the effects of auroral precipitation extend beyond the observed latitude band in which significant (~5 kR) H₂-Lyman and Werner band auroral emission have been observed by the Voyager UVS3. The observed H_2 auroral emission imply an energy input of ~ 0.5 erg cm⁻² s⁻¹ (in the 78°-81.5 °N and S latitudes) on Saturn which is about a factor of 10 lower than in the jovian auroral region.

An electron precipitation event composed of 2 keV electrons with a flux of 1.5×10^8 cm⁻² s⁻¹ could reproduce the 3-5 kR of H₂-Lyman and Werner band emission seen by the UVS³. Such an aurora produces a model ionosphere with a peak electron density of 2×10^6 cm⁻³ near 2,400 km when the effects of the charge exchange reaction $(H^+ + H_2 \ (v' \ge 4))$ are omitted. However, if a rate constant of 10^{-9} cm³ s⁻¹ is assumed for the reaction of H⁺ with H₂ ($v' \ge 4$), and a vibrational temperature of \sim 2,000 K, the peak electron density can be brought into rough agreement with the RSS high latitude ionosphere measurements.

Even if the loss of H⁺ by charge exchange with H₂ $(v' \ge 4)$ could explain low peak electron density in the high, non-auroral latitudes, similar low peak electron densities have been measured by the Pioneer 11 spacecraft near 10 °S latitude^{2,12} also, and they apparently need an alternative explanation due to

the unlikely occurrence of a significant vibrationally excited H₂ population in the Saturn equatorial ionosphere. The 700 R intensity of the non-auroral H2 bands measured by the UVS3 implies a planetwide precipitation of electrons resulting in a relatively low energy deposition rate of 1.3×10⁻² erg cm⁻² s⁻¹ on Saturn. Relatively good agreement between the Pioneer equatorial and the Voyager high latitude Saturn ionospheric data suggests a common H+ loss process missing from current theoretical models. Moreover, the loss of the major ion H⁺ after the charge exchange with vibrationally excited $H_2(v' \ge 4)$ even in the high latitudes is only a remote possibility as the measured ionosphere is $\sim 5^{\circ}-10^{\circ}$ removed from the auroral latitude band.

The most obvious choice for reconciling the calculations and the measurements is an ion-molecule reaction which would convert some of the H+ into relatively short-lived molecular ions. Although methane reacts rapidly with H⁺ to form molecular ions, it is not distributed high in the atmosphere due to the relatively low value of the eddy diffusion coefficient, $K_h \sim$ $10^6 \,\mathrm{cm^2 \, s^{-1}}$. Even an extremely high $K_h \ (\sim 10^9 \,\mathrm{cm^2 \, s^{-1}})$ falls short of the required H⁺ loss rate⁷. An alternative explanation is that water vapour in the rings could provide an important loss to the ionospheric H⁺ (ref. 14). The OH would, however, be concentrated in the region near the rings suggesting a latitudinal variation in the OH + H⁺ loss process, a variation not supported by the Pioneer and Voyager data. Furthermore, the large OH production rates might force unacceptable limits on the longevity of the rings. We also find that the depletion of the peak electron density due to the ring shadow occurs in low latitudes; the effect, however, is minimal (≤10% depletion in the electron density) at the latitudes of the Pioneer observations⁷

There is no adequate common explanation for the low peak electron densities observed at both the low and high Saturn latitudes. Dynamical effects may have an important role in the low latitude ionosphere and auroral effects may be important at high latitudes. However, some as yet unknown H⁺ loss process may be the controlling factor at all Saturn latitudes.

The location of the peak in electron density seems to be ~500 km higher than calculated (Fig. 1); this is, however, questionable as the calculated peak is quite broad. But many theories for reconciling this apparent discrepancy are possible. Calculations indicate that an average diurnal vertical drift velocity of $\sim 14 \,\mathrm{m \, s^{-1}}$ for H⁺, produced by an electrical field of \sim 3 mV m⁻¹, southward neutral winds of \sim 140 m s⁻¹, and/or vertical winds of $\sim 14 \text{ m s}^{-1}$ are capable of raising the peak by 500 km (refs. 7, 15).

C₃H₈ and C₃H₄ in Titan's atmosphere

W. C. Maguire, R. A. Hanel, D. E. Jennings, V. G. Kunde & R. E. Samuelson

Goddard Space Flight Center, Greenbelt, Maryland 20771, USA

Four bands of propane C_3H_8 and two of methyl acetylene C_3H_4 have been identified in the Voyager IR spectrum of Titan. Stratospheric abundances of 2×10^{-5} for C_3H_8 and 3×10^{-8} for C_3H_4 have been determined for the mid-latitude region. A feature at 1,154 cm⁻¹, previously assigned solely to CH₃D, is now identified at least in part due to C₃H₈.

THE Voyager 1 IR instrument (IRIS)1 obtained several hundred spectra of Titan when the angular diameter of the disk was at least five times the angular field of IRIS. Spectra of the centre of

the disk, the polar regions, and both limbs all revealed the signatures of many hydrocarbons and of HCN in emission, indicating the presence of these gases in a warm stratosphere. In

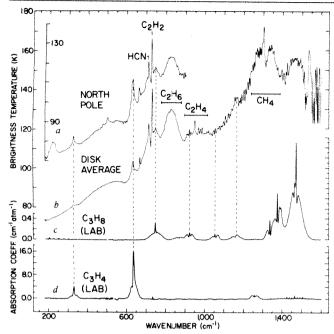

Fig. 1 Comparison of observed Titan spectrum $(4.3 \text{ cm}^{-1} \text{ resolution})$ with laboratory measurements $(2 \text{ cm}^{-1} \text{ resolution})$ at room temperature of C_3H_8 and C_3H_4 . a, An average of 29 spectra from the north polar region of Titan. b, An average of 346 dayside spectra, principally from the centre of the disk but also including data from latitudes as high as 60° N or S. Laboratory spectra of C_3H_8 (c) and C_3H_4 (d) are also shown.

some cases firm identifications and estimates of the abundances were obtained; in other cases, such as for C_3H_8 and C_3H_4 only tentative identifications were made². We provide here additional spectroscopic evidence for the existence of C_3H_8 and C_3H_4 in Titan's stratosphere and give abundance estimates using our laboratory spectra.

Titan and laboratory spectra

Two Titan spectra, containing common strong features, are shown in Fig. 1: the 'disk average' is the average of 346 individual spectra taken near the centre of the disk at a spatial resolution between 1/5 and $\sim 1/50$ of the disk diameter; the average emission angle is $\sim 35^{\circ}$. The signal-to-noise ratio is ~ 430 at 250 cm⁻¹, ~ 130 at 800 cm⁻¹, ~ 16 at 1,000 cm⁻¹, and ~ 35 at 1,500 cm⁻¹. The 'north pole' spectrum is an average of 29 spectra recorded at 68° latitude with an average emission angle of 63.4° . The signal-to-noise ratio is lower in this spectrum, ~ 125 at 250 cm⁻¹ and 35 at 800 cm⁻¹. The behaviour of the continuum emission between 200 and 600 cm⁻¹ is discussed elsewhere³.

The laboratory spectra were recorded at room temperature in two segments: $200-500~\rm cm^{-1}$ and $400-1,600~\rm cm^{-1}$. For C_3H_8 the pressure of the sample was 994 mbar for the low and 404 mbar for the high frequency region. For C_3H_4 , the pressures were 47 mbar for the low and 9.3 mbar for the high frequency region. Sample runs were ratioed with empty cell runs to produce transmission spectra from which absorption coefficients were derived (shown in Fig. 1). Band designations, wavenumbers and band strengths are listed in Table 1 for C_3H_8 and C_3H_4 for the observed $200-1,600~\rm cm^{-1}$ range. Several combination bands at $1,255~\rm cm^{-1}$ of C_3H_4 also appear in Fig. 1 in the laboratory spectrum.

Comparison of Titan and laboratory spectra

The average disk spectrum shows weak but definite spectral features of the C_3H_8 fundamentals at 748, 922, 1,054 and 1,158 cm⁻¹ (dashed lines in Fig. 1). The R branch of C_2H_2 is superimposed on the propane band but the 748 Q-branch of C_3H_8 is clearly present. The weaker bands at 922, 1,054 and 1,158 cm⁻¹ are all visible although in a spectral region where C_2H_4 and other hydrocarbons have features of comparable

strength. We have modelled the bands of CH₄, C₂H₂, C₂H₄, C₂H₆ and CH₃D in the 700–1,400 cm⁻¹ range and found that none of these gases can account for the spectral features now assigned to C₃H₈. Comparison of the spectra also shows that a feature at 1,154 cm⁻¹, which has previously been identified⁴ as due only to CH₃D, is due principally to C₃H₈. The ν_4 Q-branch of CH₃D appears to ride on this feature. The strongest C₃H₈ band in the laboratory spectrum at 1,400 cm⁻¹ shown in Fig. 1 shows no corresponding feature in the Titan spectrum, partly because CH₄ and many other hydrocarbons have strong and overlapping bands in this spectral interval, and partly because the emission originates at about the 6 mbar level where thermal contrast is greatly reduced (Fig. 2).

The disk spectrum and to a greater extent the polar spectrum show the fundamentals of C_3H_4 at $328~cm^{-1}$ and at $633~cm^{-1}$. These features are associated with the same gas because they tend to exhibit similar behaviour with position on the disk, decreasing in strength with increasing distance from the north polar region. They also show identical behaviour in scans across the limb (not shown), rising and falling in unison as each scan proceeds from space to well onto the disk. No signatures of the combination bands at $1,200-1,400~cm^{-1}$ are expected because of their weakness and the above reasons for C_3H_8 .

The identification of C_3H_4 is made firmer by comparing the relative strengths of the features at 328 and 633 cm⁻¹ in the Titan spectra with those in the laboratory spectra. Figure 2 shows most of the mass of gaseous C_3H_4 must be between the condensation point ($T \sim 110$ K; $P \sim 28$ mbar) and a point one pressure scale height above ($T \sim 150$ K; $P \sim 10$ mbar). Thus the temperature of the bulk of C_3H_4 is ~ 130 K. However, the peak brightness temperature observed in the spectrum (Fig. 1) is well below this temperature. Because the Q-branch width is comparable to the IRIS spectral resolution, it follows that the bands are optically thin, and the Q-branch intensity can be approximated by

$$I_{\nu} = \varepsilon_{\nu} B_{\nu} (130 \text{ K}) \tag{1}$$

where the emissivity of the C_3H_4 layer, ε_{ν} , is the product of the gas density and band strength and B_{ν} is the Planck function at 130 K. The band intensity ratio is therefore given by

$$\frac{I_{633}}{I_{328}} = \frac{S_{633}B_{633}(130 \text{ K})}{S_{328}B_{328}(130 \text{ K})}$$
(2)

where S is the band intensity. The Planck function ratio in equation (2) is $\sim 1/4$, while, from the laboratory spectrum in Fig. 1, $S_{633}/S_{328} \sim 4$ (see Table 1); thus the calculated value for I_{633}/I_{328} is ~ 1 provided the band strength ratio is approximately independent of temperature between 130 and 273 K. On the other hand the brightness temperature spectrum of 68° N (see Fig. 1, ref. 5) indicates that the observed value of I_{633}/I_{328} is ~ 1.2 , depending on the exact location of the continuum: this agreement is consistent within the uncertainties involved.

Abundance determinations

For normal viewing, the solution to the equation of transfer over a narrow spectral range $\Delta \nu$ can be written

$$I_{\Delta\nu} \simeq \int_{P} B_{\Delta\nu} \frac{\partial}{\partial P} \times \left[\int_{\nu'}^{\nu} \phi(\nu - \nu') \exp\left\{ - \int_{P'} \left(\sum_{i} \sum_{i} q_{i} k_{ji} (\nu' - \nu_{i}) \right) \frac{\mathrm{d}P'}{g} \right\} d\nu \right] dP \quad (3)$$

where I is the observed radiance, $\Delta \nu$ is the spectral resolution, ϕ is the instrument convolution function, B is the Planck function, g is the acceleration due to gravity, P is the pressure, and k is the mass absorption coefficient of a gas with a mole fraction q. The summations are over all gases j and all contributing lines i of a single gas. The approximation is very good when $\Delta \nu$ is small because B is essentially constant across such a narrow spectral interval.

Solving for q requires first that the vertical thermal profile of the atmosphere be determined. Second, the vertical distributions and mole fractions of all absorbing gases must be specified; initially the fraction q will be a trial value. Third, the transmission functions of all absorbing gases are calculated. Finally, an iteration is performed on q until equation (3) is satisfied.

We have adopted the shape of the radio occultation profile⁶ between 1,600 and 10 mbar, normalizing it to a surface temperature of 94 K. This profile has been extrapolated to 1 mbar using IRIS data covering the 1,250-1,310 cm⁻¹ range. Methane, the major emitter in this region, is assumed to be uniformly mixed.

Previous abundance determinations² using a line-by-line transmission function program have specified the mixing ratios for C₂H₆, C₂H₂, and HCN. Each gas was assumed to be uniformly mixed down to its condensation level, below which it was reduced to vanishingly small amounts. The cutoff was 50 mbar for C₂H₆ and C₂H₂ and 10 mbar for HCN. To adjust the spectral continuum to the data a stratospheric aerosol was added above 5 mbar, assigned an optical depth of 0.01 at 700 cm⁻¹ and made to increase linearly to 0.05 at 1,400 cm⁻¹. The exact location of the aerosol is unimportant as long as it is optically thin³.

For C_3H_8 , a synthetic spectrum was constructed for the ν_{21} band at 748 cm⁻¹. The band intensity of ν_{21} was measured from the 2 cm⁻¹ resolution laboratory spectra to be 10.1 ± 1.0 cm⁻² atm⁻¹ at 300 K. Other molecular parameters are from refs 7 and 8. Because the distribution of intensities within a 4.3 cm⁻¹ interval is less important to the present analysis than the integrated intensity in this interval, only representative line positions and intensities were used to fit our room-temperature laboratory spectrum. No molecular spectroscopic analysis was performed. Propane was also assumed to be uniformly mixed down to 50 mbar in the model, below which its abundance was set to 0. Equation (3) was iterated until convergence was reached for $q(C_3H_8)$. We infer

$$q(C_3H_8) \sim 2 \times 10^{-5}$$
 (4)

for the disk average which should be accurate to within a factor

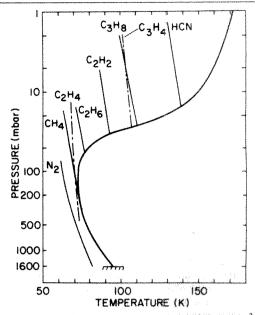

Fig. 2 Vertical temperature profile of Titan's atmosphere $^{3.6}$ and the condensation curves of N_2 and several hydrocarbons with mole fractions listed in Table 1 of ref. 5. Uniform mixing is assumed throughout the stratosphere. HCN will condense at about 15 mbar and C_2H_6 at about 60 mbar. C_2H_4 will not condense at all in the assumed concentration. The condensation products are solid particles for HCN, C_3H_4 , C_2H_2 , C_2H_6 and CH_4 and liquid droplets for C_3H_8 . Very little gas will exist below the condensation point because of the steepness of the temperature profile and vapour pressure curves.

of three. The major sources of error involve the imprecise vertical modelling of the other hydrocarbons and the aerosol, and an uncertain $748 \, \mathrm{cm}^{-1} \, Q$ -branch strength of C_3H_8 . Because the entire $748 \, \mathrm{cm}^{-1}$ band is weak, small errors in the relatively large background continuum lead to large errors in the inferred C_3H_8 mixing ratio. The concentration of C_3H_8 seems to be fairly constant over the disk.

We could now determine the mixing ratio of C_3H_4 from equation (3) if we knew the related values of $k(\nu)$ for this gas. Fortunately the integrated ν_9 band intensity and Q-branch intensity at 633 cm⁻¹ measured from the laboratory spectra is sufficient for obtaining a good approximation to the mixing ratio when C_3H_4 is optically thin throughout this band, as it is for Titan. We can expand the transmission function in equation (3) in a power series and retain only the first two terms. On inverting the orders of integration and summation in equation (3) we have

$$\int_{\nu'} \phi(\nu - \nu') \exp\left[-\int_{P} \sum_{i} \sum_{i} q_{i} k_{ji} (\nu' - \nu_{i}) \frac{\mathrm{d}P}{g}\right] \mathrm{d}\nu'$$

$$= \int_{\nu'} \phi(\nu - \nu') \left[1 - \frac{1}{g} \int_{P} \left(\sum_{i} \sum_{i} q_{i} k_{ji} (\nu' - \nu_{i})\right) \mathrm{d}P\right] \mathrm{d}\nu'$$

$$= 1 - \frac{1}{g} \int_{P} \left[\sum_{i} \sum_{i} q_{i} \left(\int_{\nu'} \phi(\nu - \nu') k_{ji} (\nu' - \nu_{i}) \mathrm{d}\nu'\right)\right] \mathrm{d}P \quad (5)$$

The second term on the right hand side is the optical depth τ_{ν} . On integrating over a spectral interval $\delta \nu$ we obtain

$$\delta \nu \tau_{\delta \nu} = -\frac{1}{g} \int_{P} \left(\sum_{i} \sum_{j} q_{j} k_{ji} \right) dP \tag{6}$$

where k is the integrated strength of an individual line and $\tau_{\delta\nu}$ the optical depth averaged over $\delta\nu$. If we restrict $\delta\nu$ to the width of the Q-branch of a single gas, equation (6) becomes approximately

$$\tau_O = -\frac{S^O}{g} \int_{g} q \, dP \,, \tag{7}$$

where S^O is the Q-branch strength and τ_O is the Q-branch optical depth of the gas. Equation (7) is an excellent approximation as long as there is minimal saturation (that is the gas is

everywhere optically thin), and the strength of the Q-branch is insensitive to temperature. The former is true for the 328 and 633 cm⁻¹ C₃H₄ bands on Titan, while the latter is true for fundamental bands generally, for which the lower state energies are small. The Q-branch strength of C₂H₂, for example, increases from 356 to only 369 cm⁻² atm⁻¹ over the temperature range 300-150 K. If we restrict solutions of q to those for which there is uniform mixing down to some cutoff level, equation (7) becomes

$$\tau_Q = \frac{P}{g} q \frac{S^Q}{\delta \nu} \tag{8}$$

where P is less than the atmospheric pressure at the condensation level, provisionally assumed to be 50 mbar for C₃H₄.

We could substitute equation (8) back into equation (3) and solve for q(C₃H₄) but because the available line-by-line program cannot readily accept a hybrid combination of transmission functions, the following artifice has been adopted. Available line parameters for the 729 cm⁻¹ C₂H₂ Q-branch replace those for the 633 cm⁻¹ C₃H₄ Q-branch. Equation (3) is then iterated and a fictitious mole fraction q^* is determined. The corresponding Q-branch optical thickness derived from equation (8) is correct, however, as long as it is small (no saturation), because it was obtained by fitting the calculations to observed data. Equations (5)-(8) demonstrate that the Qbranch optical thickness is independent of the number, strength, and way in which the individual lines are distributed in the band; q is adjusted accordingly. Hence for optically thin layers qS^Q is an invariant which depends only on the observations and the background opacity. This enables us to obtain the actual C₃H₄

abundance from the expression

$$q(C_3H_4) = \frac{S^O(C_2H_2)}{S^O(C_3H_4)}q^*$$
 (9)

where $S^Q(C_3H_4)$ is obtained from our laboratory data, and $q*S^{Q}(C_2H_2)$ is inferred from the strength of the 633 cm⁻¹ C_3H_4

Q-branch in the Titan spectrum. We find

$$q(C_3H_4) \sim 3 \times 10^{-8}$$
 (10)

for the disk average with an uncertainty of a factor of ~ 3 due to attendant uncertainties in modelling the vertical distribution and placement of the continuum, as well as the treatment of the overlapping C₄H₂ Q-branch at 628 cm⁻¹ (ref. 5). The reasons for the enhancement in the north are not known; one possible explanation is that the differences are associated with the north polar hood. The atmospheric hydrocarbon composition of Titan determined from Voyager IRIS data is summarized in Table 1 of ref. 5 for the disk average.

Organic chemistry is significantly different on Titan compared with that on Jupiter or Saturn partly because of a different photo- and high-energy particle radiation chemistry due to a relatively lower abundance of H₂ and higher abundances of N₂ and CH4 on Titan3, and partly because of the presence of an atmospheric sink at Titan's surface 9-14

C₄H₂, HC₃N and C₂N₂ in Titan's atmosphere

V. G. Kunde, A. C. Aikin, R. A. Hanel, D. E. Jennings, W. C. Maguire & R. E. Samuelson

Goddard Space Flight Center, Code 693.2, Greenbelt, Maryland 20771, USA

The compounds C_4H_2 , HC_3N , and C_2N_2 have been detected in trace amounts in the stratosphere of Titan. The identification of two compounds containing nitrogen, in addition to HCN, provides further evidence for the abundance of free N_2 on Titan.

THE Titan atmosphere is characterized by hydrocarbon and nitrogen-containing organic compounds in an atmosphere which near the surface is predominantly composed of molecular nitrogen, methane, molecular hydrogen and possibly argon¹. Molecules containing oxygen have not been detected. Many organic compounds have now been identified in the stratosphere of Titan from ground-based and spacecraft IR spectroscopic observations. The first hydrocarbon identification was the ground-based observation of methane² (CH₄). Subsequent ground-based measurements identified ethane³ (C₂H₆), acetylene⁴ (C₂H₂) and ethylene⁵ (C₂H₄). Strong IR emissions due to these gases have also been observed with the IR instrument (IRIS)6 on Voyager 1. The IRIS spectrum also indicates the presence of hydrogen cyanide (HCN), methyl acetylene (C₃H₄), and propane^{6,7} (C₃H₈). We now identify three additional organic compounds: diacetylene (C₄H₂), cyanoacetylene (HC₃N), and cyanogen (C₂N₂).

Observations

Voyager 1 took IR measurements of the atmosphere of Titan from ~ 8 h before to ~ 3 h after closest approach. An average of 346 spectra, mostly from the centre of the disk but including data from latitudes as high as $\pm 60^{\circ}$, is shown in Fig. 1. The average emission angle is ~35°. Strong emission features associated with stratospheric gases appear above a background continuum (see Fig. 1 and Table 1 which also indicate weaker emission features due to C₃H₄ and C₃H₈). The high latitude spectrum is an average of 30 individual spectra obtained at 68° N latitude near or on the dark polar hood observed in Voyager images⁸. The average emission angle is ~63°. Several features are evident in the 200-700 cm⁻¹ region of the 68° N spectrum but not in the midlatitude disk average (220, 233, 500, 663 cm⁻¹). Other features are enhanced in the high polar region (328, 628, 633 cm⁻¹). Some enhancement is caused by the higher emission angle of the north polar spectrum compared

with that of the spectra recorded further south. However, in view of the low stratospheric temperatures in the north, the strong enhancement of some spectral features implies a genuine enrichment of these species at high northern latitudes. Differences in temperatures and chemical processes associated with the polar hood may be responsible for the enrichment.

The limb spectrum shown in Fig. 2 is an average of three individual spectra taken at grazing incidence above the north polar cap. The tangent ray defining the centre of the instrument field of view passes ~ 330 km above the surface of Titan at its closest point, while the diameter of the field of view at this point is ~ 190 km. Thus, there is considerable space contamination in the spectrum, which depresses the background continuum relative to the sharp emission features producing clear separation between the 220 and 233 cm⁻¹ features.

Identification of C₄H₂, HC₃N and C₂N₂

After accounting for the emission features of C_3H_4 , HCN, C_2H_2 , C_3H_8 , C_2H_6 , C_2H_4 , and CH₄, several prominent features still remained unidentified in the 200–700 cm⁻¹ region of the IRIS spectra. The sharp appearance of these features (220, 233, 500, 628, 633 cm⁻¹) suggested association with Q branch absorptions of minor stratospheric constituents.

The assignment of these five unidentified spectral features to C₄H₂, HC₃N and C₂N₂ was based on: (1) a correspondence in wavenumber and in the shape of the emission feature with laboratory spectra of the candidate molecules; (2) the apparent agreement of the relative intensities of the features with the corresponding strengths derived from the laboratory spectra if the candidate molecule has more than one feature in the observed spectrum. We only investigated gases which were considered possible constituents of the atmosphere of Titan. A list of potential constituents was assembled from organic chemistry studies involving photochemical and energetic particle bombardment processes⁹⁻¹¹. Spectra in the 200-1,400 cm⁻¹ region were obtained for these potential atmospheric constituents at nearly the same spectral resolution as Voyager IRIS. (The laboratory spectra were obtained at 2 and 4 cm⁻¹ resolution with a Fourier transform spectrometer operated by the Optics Branch, Goddard Space Flight Center. Samples were contained in a 3-cm length cell at pressures ranging from 11 to 140 torr. Sample temperatures were ambient (300 K).)

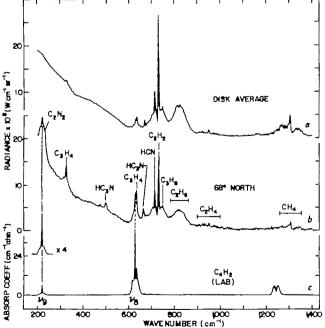

Fig. 1 Comparison of laboratory and Titan radiance spectra. The disk average spectrum (a) represents mainly mudiatitude regions on Titan while the 68° N spectrum (b) is of a region near or over the northern polar cap. Several emission features in the 200-700 cm⁻¹ region are enhanced in the 68° N spectrum. c, A laboratory spectrum for diacetylene (C₆H₂)

 C_4H_2 is expected to be present in the upper atmosphere of Titan as a result of methane photolysis and hydrogen escape, leading to C_2H and to the production of C_4H_2 by the reaction $C_2H+C_2H_2$. The two features in the IRIS spectrum at 220 and 628 cm⁻¹ correspond to the Q branches of the ν_p and ν_g fundamental vibration-rotation bands of C_4H_2 , respectively¹². These two features are marked in Fig. 1 but may be seen most distinctly in the high air mass spectrum of Fig. 2. The 220 cm⁻¹ C_4H_2 feature is partially overlapped by the 233 cm⁻¹ C_2N_2 emission and the 628 cm⁻¹ feature by the C_3H_4 emission at 633 cm⁻¹. However, the 4.3 cm^{-1} resolution allows identification of C_4H_2 . The intensity ratio for the two C_4H_2 features in the observed spectrum may be approximated by⁷

$$\frac{I_{220 \text{ cm}^{-1}}}{I_{628 \text{ cm}^{-1}}} = \frac{S_{220}^O}{S_{628}^O} \frac{B_{220}(130 \text{ K})}{B_{628}(130 \text{ K})}$$

where S is the strength of the Q branch of the molecular band, and B is the Planck function at 130 K. Q branch strengths derived from laboratory data yield an intensity ratio of ~ 0.74 , which agrees with the observed intensity ratio of ~ 0.72 for the north limb spectrum (Fig. 2). The observed intensity ratio is therefore consistent with the C_4H_2 identification. The C_4H_2 band at 1,250 cm⁻¹ is too weak to appear in the Titan spectrum.

 HC_3N is expected in Titan's atmosphere from the reaction of CN with C_2H_2 and C_2H_4 , where the CN is produced from the dissociation of HCN and the C_2H_2 from methane photolysis°. As indicated by comparison with the laboratory spectrum in Fig. 2, the HC_3N emissions from the ν_6 and ν_5 fundamental vibration-rotation bands^{13,14} at 500 and 663 cm⁻¹, respectively, are easily identified. The intensity ratio of the two features $(I_{500 \text{ cm}}^{-1}/I_{663 \text{ cm}}^{-1})$ are approximately the same in the observed and the laboratory spectra (\sim 0.8), thus strengthening the HC_3N identification. The HC_3N band at 1,310 cm⁻¹ is too weak to appear in the Titan spectrum.

 C_2N_2 is predicted to occur in the Titan atmosphere through the combination of a CN radical, either with HCN or with another CN radical. The only C_2N_2 emission feature occurring in the IRIS spectrum (Fig. 2) is the strong ν_5 fundamental band ¹³ at 233 cm⁻¹. The detection of C_2N_2 and HC₃N is consistent with experiments carried out for CH₄-N₂ mixtures ¹⁶.

The strong emission features of the three gases in the limb spectrum (Fig. 2) indicate that a large fraction of their mass is in the upper stratosphere (p < 20 mbar, T > 130 K). Additionally large concentrations are not expected to occur in the low temperature environment of the lower stratosphere due to condensation (see Fig. 2 of ref. 7). Thus we can associate the formation of these gases with photochemistry in the upper stratosphere. Crude abundance estimates for these three gases yield mole fractions between 10^{-8} and 10^{-7} , consistent with production by nitrogen ion and methane photolysis photochemistry.

Discussion and conclusion

The organic compounds observed in the atmosphere of Titan are summarized in Table 1, which also indicates the approximate

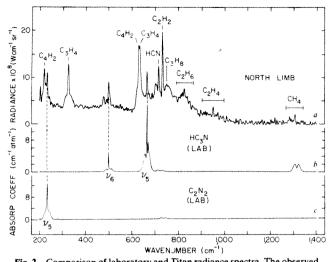

Fig. 2 Comparison of laboratory and Titan radiance spectra. The observed spectrum (a) was obtained off the limb of the planet in the northern polar cap region. The high air mass along the line of sight enhances the weak emission features, while space contamination in the field of view depresses the adjacent continuum. Laboratory spectra for cyanoacetylene (HC₃N) (b) and cyanogen (C2N2) (c) are shown.

mole fraction for each compound identified previously, as determined from analysis of the disk average spectrum. These compounds originate by reactions of methane and nitrogen radicals in a predominantly nitrogen atmosphere. Although Titan's location at 9.35 AU reduces the solar flux by a factor of 87 compared with the flux at the Earth, dissociation of significant quantities of methane still occurs due to Ly α radiation. Titan is located within the Saturn magnetosphere and lacks a shielding magnetic field. This causes energetic electrons and

protons to ionize and dissociate the principal atmospheric constituents. Bremsstrahlung extends the effective penetration depth of energetic electrons down to an altitude of 130 km. In addition to charged particles from Saturn's magnetosphere Titan is bombarded by galactic cosmic radiation, consisting mostly of protons in the GeV range, which penetrate to the surface. Particle ionization is expected to lead to neutral fragments and ions, including CH, N, CH₂, N₂⁺, N⁺, CH₄⁺, and CH₃. Subsequent ion-molecule reactions involving methane, molecular hydrogen, and molecular nitrogen lead to complex neutral hydrocarbons. The various energy sources, acting over a long period of time, have formed a complex array of hydrogencarbon-nitrogen compounds.

The wide variety of organic compounds, with fairly high abundances of C₂H₂ and C₃H₈, indicates that the chemistry of Titan is significantly different from that of Jupiter and Saturn. One reason is the low H_2 abundance $(\sim 0.2\%)^1$ which prevents rapid recycling of CH₄ (ref. 18), and yields higher relative levels of the methane photolysis reactive radicals (CH₂, CH₃, C₂H). Also, these and the CN radical from the dissociation of HCN, do not react with the major constituent N2 and thus are available to react with minor hydrocarbon species to form more complex compounds. Additionally, the reduced solar flux leads to an increased lifetime of minor atmospheric constituents against photodissociation.

Many of the Titan constituents have been detected in inter-stellar sources 18-20. Among those with non-zero dipole moments (HCN, HC₃N, C₃H₄, and C₃H₈) only C₃H₈ has not been detected at radio wavelengths for the interstellar sources.

We thank J. Heaney and K. Stewart for operating the laboratory spectrometer, and J. Faris for laboratory assistance. The diacetylene sample was supplied by H. Okabe. Partial support was provided by the NASA Planetary Atmospheres Program.

Mean molecular weight and hydrogen abundance of Titan's atmosphere

R. E. Samuelson, R. A. Hanel, V. G. Kunde & W. C. Maguire

Goddard Space Flight Center, Code 693.2, Greenbelt, Maryland 20771, USA

The 200-600 cm⁻¹ continuum opacity in the troposphere and lower stratosphere of Titan is inferred from thermal emission spectra from the Voyager 1 IR spectrometer (IRIS). The surface temperature and mean molecular weight are 94 K < $T_{
m G}$ <97 K and 28.3 < M < 29.2 AMU, respectively. The mole fraction of molecular hydrogen is 0.002 ± 0.001 , which is equivalent to an abundance of $\sim 0.2 \pm 0.1$ km amagat.

THERMAL inversion in Titan's atmosphere has been demonstrated by narrow band IR photometry1.2 and spectrophotometric data3 which showed that at least methane, ethane and probably ethene exist in a warm stratosphere overlying a colder background. Danielson et al.4 and Caldwell5 quantitatively explained the major features of the thermal emission spectrum using simple inversion models.

Models with a deeper atmosphere had also been suggested. But even in the model proposed by Hunten⁶, which was remarkably accurate in its thermal and compositional predictions, it was accepted that methane clouds and photochemically

induced smog would obscure the atmosphere below the tropopause. McCarthy et al.7 interpreted their data between 330 and 625 cm⁻¹ as being consistent with an inversion model. An optically opaque base, either the surface or dense clouds, was assumed to be roughly at a temperature of 74 K, below which little, if any, information was available.

This situation changed when Voyager 1 IR data showed limb darkening over the 200-600 cm⁻¹ spectral range⁸. The radiance at small emission angles (the angle at the surface between the direction of viewing and the surface normal) was found to be larger than that for large angles near the limb. This could occur

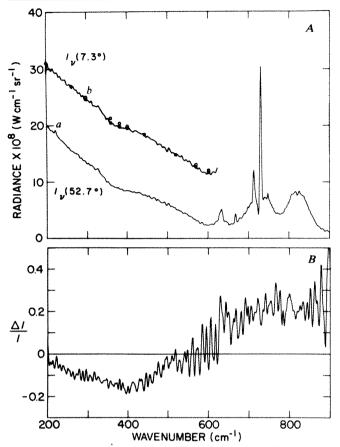

Fig. 1 A. a, average of 29 spectra near the daytime east limb. The average emission angle is 52.7° and the mean latitude is 7.2°N. b, Average of 10 spectra near the sub-spacecraft point. The average emission angle is 7.3° and the mean latitude is 8.3°N. Theoretical fits for a hydrogen mole fraction q = 0.002 (\blacksquare); q = 0 (O). Values are displaced 10 radiance units upwards for clarity. B, northern low-latitude spectral limb function: $\Delta I/I = 1 - I_{\nu}(7.3^{\circ})/I_{\nu}(52.7^{\circ})$.

only if the observed radiation originated principally below the temperature minimum, from the troposphere.

The observed spectral limb function is

$$\frac{\Delta I}{I} = \frac{I_{\nu}(52.7^{\circ}) - I_{\nu}(7.3^{\circ})}{I_{\nu}(52.7^{\circ})}$$
(1)

where $I_{\nu}(\theta)$ is the radiance at wavenumber ν and emission angle θ . $I_{\nu}(7.3^{\circ})$ and $I_{\nu}(52.7^{\circ})$ are averages of 10 and 29 spectra, respectively, and are shown in Fig. 1 with the spectral limb function.

We have found that at low latitudes the limb function is symmetric about the sub-spacecraft meridian, indicating a lack of diurnal and longitudinal variation, although Flasar $et\,al.^9$ find evidence for a slight latitudinal inhomogeneity at $\sim 10^\circ$ south latitude where a weak opacity transition at $200~\rm cm^{-1}$ seems to occur. This coincides approximately with the visual brightness transition found near the equator 10 . Thus the limb function given by equation (1) should be free of horizontal inhomogeneity as the selected data sets are associated with fields of view that are small, closely grouped, and are between 0° and 15° N latitude. Because this latitude range also includes the ingress Earth occultation point, we can incorporate the radio science temperature profile 11 directly into a quantitative interpretation of our data.

Models

The two spectral averages indicated in equation (1) yield independent information, principally because the large difference in emission angles ensures that different effective emission levels in the atmosphere are being sampled. Thus at each wavenumber two independent parameters characterizing the radiative properties of the atmosphere can be inferred. We have chosen for these the optical thicknesses of the stratosphere $\Delta \tau_{\rm S}$ and tropopause $\Delta \tau_{\rm T}$.

We restrict the computational models to the range 200–600 cm⁻¹. Solutions for higher wavenumbers do not converge, probably because of insufficient signal below the tropopause. A simple exponential law of absorption is assumed, which is adequate as long as clouds, hazes and pressure-induced absorption by gases are the only opacity sources. Thus we avoid the spectral ranges 205–255 cm⁻¹, 305–355 cm⁻¹, 460–515 cm⁻¹ and above 605 cm⁻¹, where sharp-line spectral features are seen in the spectra⁸. The formal solution to the equation of transfer

$$I_{\nu} = \int_{0}^{\infty} B_{\nu}(\tau) e^{-\tau/\mu} \frac{\mathrm{d}\tau}{\mu} \tag{2}$$

can be expressed numerically by

$$I_{\nu}(\mu_{k}) = \sum_{i=1}^{n} B_{\nu}(\tau_{i}) \left\{ \exp\left[-\sum_{j=i+1}^{n} \frac{C_{j}}{\mu_{k}} \Delta t_{j}\right] \right\}$$

$$\times \left\{ 1 - \exp\left[-\frac{C_{i}}{\mu_{k}} \Delta t_{i}\right] \right\} (k = 1, 2)$$
(3)

where $B_{\nu}(\tau_i)$ is the Planck function at wavenumber ν (constant across layer i), τ is the optical depth, μ_k the direction cosine of the kth emission angle, n the number of layers (including the ground), and

$$\Delta \tau_i = C_i \Delta t_i (i = 1, \dots, n) \tag{4}$$

is the optical thickness of layer i. The relative vertical distribution of opacity is specified in the model by the reduced optical thickness Δt_i . The C_i in equations (3) and (4) are then solved by an iterative technique. For each wavenumber interval the C_i provides multiplication factors which convert the assumed relative optical thicknesses, Δt_i , into absolute values $\Delta \tau_i$. Because we have only two free parameters available we assign one value to the stratosphere and the other to a layer at the tropopause; the latter is about the level where we expect the upper boundary of methane clouds. The height of the stratospheric layer as well as its vertical extent is varied from case to case. In some cases a third multiplier C=1 is specified in the troposphere to accommodate pressure-induced absorption.

The temperature profiles are patterned after the radio occultation ingress profile (ref. 11 and G. L. Tyler and G. Lindal,

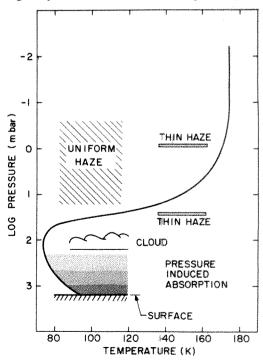

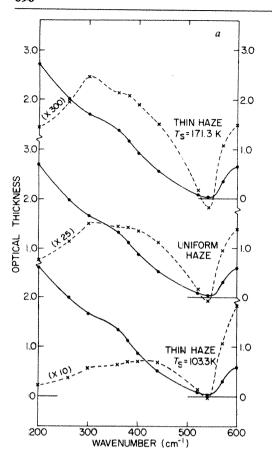

Fig. 2 Temperature profile corresponding to our nominal model. The shape between 10 and 1,600 mbar is taken from data provided by G. L. Tyler and G. Lindal and normalized to a surface temperature $T_{\rm G} = 95$ K. The extrapolation above 10 mbar is forced to be consistent with brightness temperatures observed in the 1,304 cm⁻¹ $\nu_{\rm c}$ band of methane in the IRIS spectra.

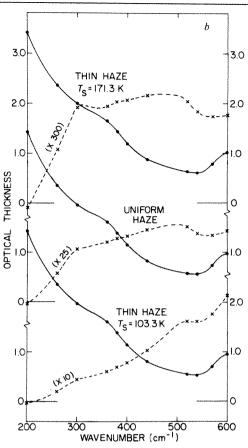

Fig. 3 Optical thicknesses of the stratosphere $\Delta \tau_{\rm S} (- \times - \times - \times)$ and tropopause $\Delta \tau_{\rm T} (- - - \times)$. The three models for $\Delta \tau_{\rm S}$ are expanded by factors of 300, 25, and 10 for clarification. Surface temperature: a, $T_{\rm G} = 94~{\rm K}$; b, $T_{\rm G} = 96.3~{\rm K}$.

personal communication). The shape of this profile is retained, but the magnitude is normalized to different values of the surface temperature $T_{\rm G}$, which is equivalent to assuming different (constant with altitude) mean molecular weights M. Above 10 mbar the profile is extended to 0.01 mbar by extrapolating to 174 K, an asymptotically limiting value consistent with the brightness temperatures at the Q-branch of CH_4 at 1,304 cm⁻¹ in the low-latitude IRIS spectra. Partial checks using the CH_4 P-branch brightness temperatures at 1,260 cm⁻¹ show internal consistency to within \sim 3 K at the 5 mbar level. A nominal working profile with $T_{\rm G}$ = 95 K is shown in Fig. 2.

Figure 2 also shows the various forms of opacity considered in our models. The first set of models consists of one cloud layer at the tropopause and three opacity alternatives in the stratosphere: two thin haze layers located at temperatures of 171.3 K and 103.3 K, and a haze mixed uniformly throughout the stratosphere with an opacity directly proportional to the atmospheric density. Each alternative is computed separately using the radiances measured at both emission angles. The solutions are the total stratospheric and tropopause optical thicknesses $\Delta \tau_{\rm S}$ and $\Delta \tau_{\rm T}$ as functions of wavenumber, and are shown in Fig. 3 for surface temperatures of 94 K and 96.3 K. These temperatures are close to the minimum and maximum permissible values, indicating that the range of possible opacity models is bounded by those shown in Fig. 3.

Thermal opacity

Several conclusions can be inferred from Fig. 3. First, although the wavenumber dependence is not well defined, the stratospheric opacity tends to be small at all wavenumbers for all models. Thus the contribution of emission from the stratosphere is approximately

$$I_{\rm S} = B_{\nu} \Delta \tau_{\rm S} \tag{5}$$

where B_{ν} is the Planck function associated with layer $\Delta \tau_{\rm S}$. (For the uniform haze models an appropriate weighting of the Planck function must be carried out.) Because the Planck function corresponding to stratospheric temperatures is large relative to values corresponding to temperatures in the troposphere (see

Fig. 2), the stratospheric contribution to the measured radiance is not negligible despite small values of $\Delta \tau_s$, but can amount to a large fraction of the total signal. However, without an independent determination of the vertical distribution of the stratospheric haze, it is not possible to separate B_{ν} and $\Delta \tau_s$. Thus, because the wavenumber dependence of B_{ν} varies strongly over the range of stratospheric temperatures, a correspondingly large uncertainty also exists in the wavenumber dependence of $\Delta \tau_s$.

Conversely, the qualitative wavenumber dependence of the tropopause opacity is well defined independently of the way in which the stratosphere is modelled, principally because the stratospheric opacity is too small to impede or modify radiation passing through it from below. From 200 cm⁻¹ to ~540 cm⁻¹ the tropopause opacity decreases monotonically with a reversing trend observed between 540 and 600 cm⁻¹. Beyond 600 cm⁻¹ stable solutions are impossible, apparently because there molecular emission from the stratosphere dominates the spectrum.

The general increase of tropopause opacity with decreasing wavenumber below about $540~\rm cm^{-1}$ has led to two suggestions for the absorption mechanism⁸: pressure-induced absorption by various CH₄ and N₂ combinations, and absorption by methane clouds. Calculations by R. Courtin (personal communication) imply that pressure-induced absorption could supply only a few per cent of the required opacity at the low temperatures prevailing in the Titan troposphere. Other data ^{12,13} suggest CH₄ clouds to be a realistic opacity source. The observed thermal dis-

Table 1 Possible mole fractions	Possible mole fractions of different gases at Titan's surface						
Gas	Mole fraction

Ar	0.116						
CH₄	0.060						
H ₂	0.002						

The nominal model has a surface temperature of 95 K and a mean molecular weight of 28.6 AMU. The methane fraction of saturation is slightly less than 0.5. Argon ($M=40~\mathrm{AMU}$) is postulated to be present, partly because its presence sexpected on the basis of its cosmic abundance and partly because it is one of the few gases that will not freeze out at the abundance required to balance the mean molecular weight.

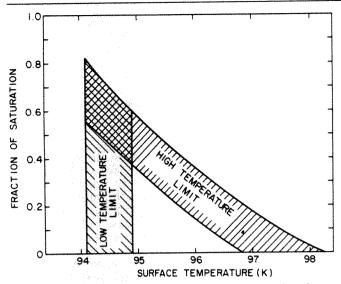

Fig. 4 Minimum and maximum allowable surface temperatures for a given fraction of methane saturation. For a constant methane mole fraction, a fractional saturation of 0.19 at the surface corresponds to complete saturation just below the tropopause. The widths of the bands for the high and low temperature limits give a measure of the uncertainties.

continuity across the equatorial region at 200 cm⁻¹ also implies that clouds contribute at least part of the opacity. Until more extensive laboratory data on liquid and solid CH₄ are considered we can only suggest that methane clouds may provide the dominant opacity in Titan's upper troposphere.

Surface temperature and mean molecular weight

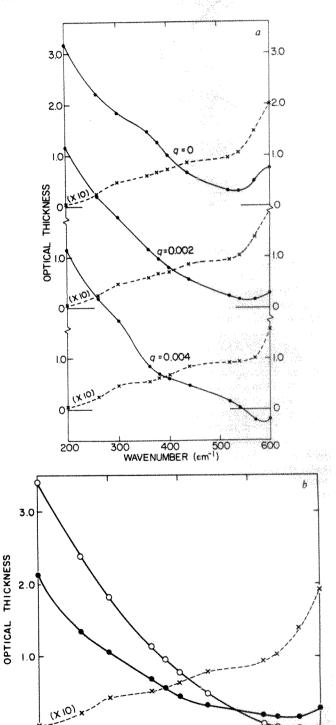

At 540 cm⁻¹, the models in Fig. 3a show a negative stratospheric opacity and a tropopause opacity that is almost zero; hence the total opacity in the atmosphere is effectively zero, and to lower the surface temperature T_G below 94 K would require both opacities to become negative. Because this is physically impossible, 94 K is a lower limit, and the observed emission at 540 cm⁻¹ is dominantly from the surface. If the actual surface temperature were lower, stratospheric emission would have to compensate to yield the measured radiance. This would cause limb brightening, contrary to what is shown in Fig. 1. On the other hand, increasing T_G to 96.3 K causes the calculated stratospheric opacity at 200 cm⁻¹ to become negative (Fig. 3b). This is a consequence of requiring the minimum atmospheric temperature to be higher than the observed brightness temperature of 74 K at 200 cm⁻¹, again a physical impossibility.

Thus the surface temperature seems to be bounded between close limits, although a few corrections need to be made. Some opacity due to hydrogen absorption is required at $540 \, \mathrm{cm}^{-1}$ and our modelling suggests that this can be achieved by raising the minimum surface temperature limit to $94.5 \pm 0.4 \, \mathrm{K}$. Noise in the data and uncertainties in the H_2 absorption coefficients account for the uncertainty in T_G .

The upper limit to the surface temperature is more uncertain. Its assessment depends first on determining an upper limit to the tropopause temperature, and then scaling this to the surface with the aid of the radio occultation profile 11. If the limb darkening of about 0.8 K observed at 200 cm 1 is due partly to multiple scattering in methane clouds, the tropopause temperature must be raised some fraction of this amount. Alternatively, if the 200 cm 1 brightness temperature discontinuity of $\sim 1 \, \mathrm{K}$ across the equator 9 is due to an opacity gradient rather than a horizontal thermal gradient, the tropopause temperature must be reduced accordingly. The upper limit to the temperature at the tropopause becomes 74 K with an estimated uncertainty of $\pm 0.5 \, \mathrm{K}$. This scales to a surface temperature upper limit of $96.3 \pm 0.7 \, \mathrm{K}$.

A further complication is introduced when a variable CH_4 mole fraction below the tropopause is considered, requiring that the mean molecular weight M also be scaled. From published data¹⁴ it is found that the condensation profile for methane

becomes tangent to the temperature profile at $T=75~\rm K$ for a methane mole fraction of $q(\rm CH_4)=0.0266$. Thus, if methane saturates anywhere it will do so at the 75 K level, resulting in a constant mole fraction of 0.0266 above this level and a larger variable fraction below it. Using the T/M value of 2.55 K $(\rm AMU)^{-1}$ at the tropopause¹¹, we find M=29.0 at $T_{\rm T}=74~\rm K$. This leads to a height-independent molecular weight of 29.4 AMU for the remainder of the atmosphere after the contribution from $\rm CH_4$ is subtracted out. On adopting the radio

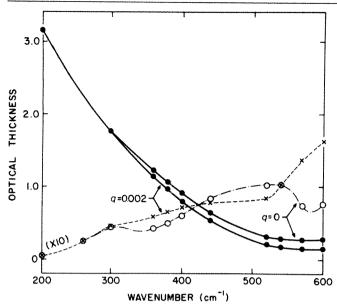

Fig. 6 Modified optical thicknesses. Smooth fits to $\Delta \tau_{\rm T}$ in Fig. 5a for two values of q are shown (——). Corresponding solutions for $\Delta \tau_{\rm S}$ are obtained by forcing a fit to the limb spectrum in Fig. 1 (——×——×, and—·—). The surface temperature is $T_{\rm G} = 95~{\rm K}$.

occultation T/M value of 3.32 K (AMU)⁻¹ for the surface ¹¹ it becomes straightforward to calculate the surface temperature for different mole fractions of methane. As the tropopause temperature of 74 K is an upper limit, the surface temperatures scaled from this value are also upper limits.

The results from these calculations are shown in Fig. 4 as a function of the fraction of methane saturation. Also shown is the lower limit to the surface temperature calculated previously. Both limits are displayed as bands to illustrate the attendant uncertainties. Any combination of surface temperature and fraction of saturation within the enclosed triangle is a legitimate solution. Values for the fraction of saturation below 0.19 are not very likely on physical grounds, however, because they correspond to methane mole fractions less than the tropopause value. The lower troposphere seems to be undersaturated with respect to methane, perhaps substantially so, although the fairly long chain of reasoning involved makes it difficult to assess the associated uncertainties. From Fig. 4, with the fraction of saturation equal to 0.19, the limits for the surface temperature

$$94 K < T_{\rm G} < 97 K \tag{6}$$

from which it follows that the limits for the mean molecular weight are

$$28.3 < M < 29.2 \text{ AMU}$$
 (7)

If the CH_4 fraction of saturation at the surface is >0.19, as is likely, the upper limits in expressions (6) and (7) must be reduced accordingly.

Tyler and Lindal (personal communication) have pointed out that the radio occultation values for T/M (ref. 11) are accurate to two significant figures but probably not to three, adding an uncertainty of about ± 0.8 AMU to the limits of M in equation (7). On the other hand, inferring the surface temperature from one that is measured at the tropopause depends essentially only on the ratio of the respective T/M values. As this ratio is better determined than the individual values of T/M (G. L. Tyler and G. Lindal, personal communications), the upper limits for the surface temperature in Fig. 4 and equation (6) are well established.

Despite the many uncertainties M is probably >28, the value for molecular nitrogen. Taking $T_G = 95$ K and $(T/M)_G = 3.32$, we find M = 28.6. If $q(CH_4) = 0.06$ at the surface (<50% of saturation; see Fig. 4) and the atmosphere is composed only of hydrogen, methane, nitrogen and argon, it is possible to construct the mole fraction for each. The results are listed in Table 1 and show a large amount of argon (~12%), although the

atmosphere remains dominantly nitrogen. Table 1 is only meant to be representative of reasonable conditions. We have no direct evidence that argon exists in the atmosphere, only that some molecular constituent higher in mass than N_2 is probably present, and argon is a plausible choice because of its inert qualities and low condensation temperature. The upper limit of 6% argon inferred by the UV experiment is not inconsistent with our suggested value.

Molecular hydrogen abundance

Superimposed on the general tropopause opacity continuum shown in Fig. 3 are two localized broad features at $360~\rm cm^{-1}$ and $600~\rm cm^{-1}$ which correspond closely to the S(0) and S(1) pressure-induced absorption lines of molecular hydrogen. We have calculated approximate absorption coefficients for the pressure-induced absorption of H_2 due to collisions with N_2 . The calculations are based primarily on the theoretical work of Birnbaum and Cohen¹⁶ for H_2 – H_2 collisions. The conversion to absorption coefficients for H_2 – H_2 collisions was accomplished by scaling the laboratory data of Kiss and Welsh¹⁷ and Kiss *et al.*¹⁸. As both the integrated absorption coefficient and the line half widths were scaled from data obtained at 195 K, there is an estimated uncertainty in the absorption coefficients of ~25% at the temperatures prevailing near the surface of Titan.

We have normalized the temperature profile in Fig. 2 to a surface temperature of 95 K, a realistic value according to Fig. 4. Induced H_2 - N_2 absorption is then added to the other sources of opacity in the radiative transfer calculations. This new opacity source has a pressure-squared dependence, most dominant in the lower troposphere. Above the tropopause the effect was neglected because it is <1% of its value near the surface.

According to the models discussed previously, the tropopause opacity calculations are basically independent of the stratospheric model adopted (see Fig. 3). This remains true when pressure-induced H_2 opacity is added to the troposphere. Figure 5a shows several solutions for the optical thicknesses of the stratosphere and tropopause for the thin haze model with $T_{\rm S}=103.3$ K. Other stratospheric models yield essentially the same results for $\Delta\tau_{\rm T}$. Thus the H_2 mole fraction seems fairly well defined if one imposes the condition that the wavenumber dependence of $\Delta\tau_{\rm T}$ be as smooth as possible. A hydrogen mole fraction $q\sim0.002\pm0.0005$ provides the smoothest fit to $\Delta\tau_{\rm T}$ of the cases examined, although the actual uncertainty in q is larger owing to the 25% uncertainty in the hydrogen absorption coefficients, leading to a final value of

$$q(H_2) = 0.002 \pm 0.001$$
 (8)

The result for q is basically independent of the stratospheric model adopted. Further tests show this to be true for the tropospheric opacity also. One such test, shown in Fig. 5b, entails a model that departs radically from the previous ones. Instead of placing all the tropospheric opacity at the tropopause, substantial pressure-induced absorption associated with a fictitious gas is introduced, which places most of the absorption near the surface. The total optical depth of this absorber is shown as a function of wavenumber in Fig. 5b. The much weaker pressureinduced absorption of H_2 with q = 0.002 is then added, and solutions for $\Delta \tau_{\rm S}$ and $\Delta \tau_{\rm T}$ are obtained as before. Although the quantitative solutions for $\Delta \tau_{\rm T}$ are substantially different from those in Fig. 5a, the shapes of the two curves corresponding to identical values of q are quite similar, showing the same degrees of smoothness. The solutions for $\Delta \tau_{\rm S}$ are nearly identical in both cases. Thus the determination of q seems to be independent of the method by which the tropospheric background opacity is modelled as long as the wavenumber dependence of the latter is smooth.

An estimate of the sensitivity of the solutions to the accuracy of the data can be obtained by replacing $\Delta \tau_{\rm T}$ with a completely smooth curve and forcing perfect fits to the limb radiances I_{ν} (52.7°) (see Fig. 1). Subjectively determined smooth fits of $\Delta \tau_{\rm T}$ from Fig. 5 for q=0 and q=0.002 are shown in Fig. 6. Solutions for $\Delta \tau_{\rm S}$ for q=0.002 and 0 are also shown. These results lead in

turn to the solutions for I_{ν} (7.3°) shown in Fig. 1 for q = 0 and q = 0.002; the observed spectrum at $\theta = 7.3^{\circ}$ is superimposed.

As Fig. 1 demonstrates, the solutions for q = 0.002 fit the data well, whereas those for q = 0 show marked departures across the S(0) line and smaller departures in the vicinity of the S(1) line. In Fig. 6 the q=0 solutions for $\Delta \tau_{\rm S}$ inversely mimic the signatures corresponding in position to the S(0) and S(1) lines. Apparently this is how the model compensates for a lack of H₂ absorption in the troposphere in the process of fitting the limb spectrum in Fig. 1 (see also equation (5)). Conversely the q = 0.002 solutions for $\Delta \tau_s$ in Fig. 6 show no such inclination, implying that the H₂ opacity has been modelled correctly.

The total depth of our model atmosphere is ~90 km amagat, yielding from equation (8) a molecular hydrogen abundance of ~0.2 km amagat. This is a factor 25 lower than Trafton's 19,20

suggested value of 5±3 km amagat, and a factor 10 lower than his lower limit. We cannot reconcile the two results. However, our value is consistent with the upper limit of 1 km amagat reported by Münch et al.21. It is also compatible with the steady-state mole fraction expected from balancing the production rate of H₂ (due to photochemical and charged particle decomposition of methane) with the H₂ loss rate (due to upward diffusion and subsequent blowoff at the top of the exosphere)6.

We thank J. Pearl for helpful discussions and L. Horn and R. Koppany for observational planning; also G. L. Tyler and G. Lindal for a numerical listing for the radio occultation ingress profile, and R. Courtin for pressure-induced absorption calculations for various CH₄-N₂ mixtures in advance of publication.

Titan's atmosphere: temperature and dynamics

F. M. Flasar, R. E. Samuelson & B. J. Conrath

Laboratory for Extraterrestrial Physics, NASA/Goddard Space Flight Center, Greenbelt, Maryland 20771, USA

In the lower atmosphere of Titan IR brightness temperatures exhibit meridional contrast ≤ 3 K. Seasonal variations are absent because of the large radiative time constant. In the upper stratosphere meridional contrasts are ~ 20 K, consistent with 100 m s⁻¹ cyclostrophic zonal winds, and the radiative time constant is short, implying a large seasonal variation in the temperature and wind field. The absence of longitudinal thermal structure implies that zonally symmetric flows effect the meridional transport of heat. A simple model yields meridional velocities ~0.04 cm s⁻¹ and vertical eddy viscosities $\sim 10^3$ cm² s⁻¹ in the lower troposphere, and meridional velocities ~ 5 cm s⁻¹ in the upper stratosphere.

COVERAGE of Titan by the IR instrument (IRIS) during the Voyager 1 encounter provided information on the global thermal structure of the satellite and its atmosphere at relatively high spatial resolution. Here we present data obtained in three spectral intervals which sample the lower troposphere and surface, tropopause, and the upper stratosphere. We discuss the meridional and longitudinal thermal structure implied by the data. Finally, we estimate radiative time constants at various levels of Titan's atmosphere and examine a class of dynamical flows which are consistent with the data.

Observations

The data were obtained over a 6-h interval when the spacecraft was within 2×10^5 km of the center of Titan and the instrument field of view was less than one-third of the satellite's 2.570 km radius. The season on Titan was close to northern spring equinox. Three spectral regions have been analysed. In the first, centred at 530 cm⁻¹, the total optical thickness of the atmosphere is $\tau \le 0.6$ (ref. 1). The major contributor to the opacity is pressure-induced absorption of molecular hydrogen from H2-N₂ collisions. As this effect is confined to a vertical range close to the ground, the 530 cm⁻¹ brightness temperature should be close to the actual surface temperature. Brightness temperatures near 200 cm⁻¹ correspond approximately to the tropopause temperature¹. The 200 cm⁻¹ opacity has been inferred to be fairly large $(\tau \ge 3)$, confined mainly to clouds, and constrained to a vertical range over which the atmosphere is essentially isothermal. Finally, the 1,304 cm⁻¹ ν_4 Q-branch of

methane is associated with emission from the ~0.3 mbar pressure level.

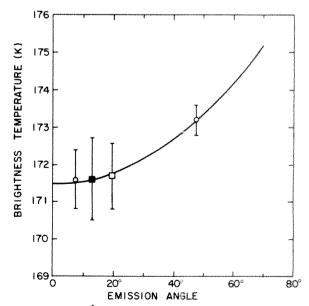

Fig. 1 1,304 cm⁻¹ low latitude limb function. O, Northern latitude daytime data; [], southern daytime data; [], southern nighttime data. Error bars include uncertainties due to noise and calibration.

Table	e 1 1,304-	-1,260 cm ⁻¹ brights	ness temperature	differences
Е	mission			
Latitude	angle	$T_{\rm B}(1,304)$	$T_{\rm B}(1,260)$	$\delta T_{\rm p}({\bf K})$
-55.0°	50.5°	169.8 ± 0.7	153.7 ± 1.7	16.1 ± 1.9
+7.5°	47.5°	173.2 ± 0.4	156.7 ± 1.3	16.5 ± 1.4
+52.6°	50.5°	168.1 ± 0.9	149.1 ± 2.1	19.0 ± 2.3

Vertical temperature gradients produce an emission angle dependence in the observed radiance, which must be removed to infer the horizontal structure in atmospheric temperature. We have therefore normalized the data in each wavenumber region to a common emission angle. Corrections at $200 \, \mathrm{cm}^{-1}$ and $530 \, \mathrm{cm}^{-1}$ were determined from a spectral limb function derived from data¹ restricted to the latitude range $0-15^{\circ}$ N. These corrections have been applied to the data at all latitudes, even though there seems to be a subtle but real meridional change in opacity across the equator. There is no rigorous justification for doing this; however, as the corrections tend to be small ($\leq 0.8 \, \mathrm{K}$ at $200 \, \mathrm{cm}^{-1}$ and $\leq 0.3 \, \mathrm{K}$ at $530 \, \mathrm{cm}^{-1}$) any corresponding systematic error should also be small.

The larger emission angle corrections at 1,304 cm⁻¹ are more reliable. Horizontal opacity inhomogeneities (due to clouds, for example) are not as likely near the 0.3 mbar level as they are at lower altitudes. Moreover, the difference between the brightness temperatures at 1,260 cm⁻¹ and 1,304 cm⁻¹, divided by the difference in altitudes at which the respective CH4 weighting functions peak, gives a crude approximation of dT/dz at each geographical location. Figure 1 depicts the emission angle corrections derived for low latitudes. Table 1 shows the brightness temperature differences $T_{\rm B}(1,304) - T_{\rm B}(1,260)$ at three widely separate latitudes where enough spectra are available for sufficient signal at 1,260 cm⁻¹. The emission angles are very similar, and the values of $\delta T_{\rm B}$ are identical to within the noise of the data. As CH₄ should be uniformly mixed at these levels, the altitude difference between weighting functions should be independent of geographical location. Thus the emission angle corrections derived for low latitudes should also be valid at high latitudes.

Other uncertainties and corrections exist. The statistical uncertainty due to noise was generally about $\pm 1\,\mathrm{K}$ at $1,304\,\mathrm{cm}^{-1}$; at $200\,\mathrm{cm}^{-1}$ and $530\,\mathrm{cm}^{-1}$ it was smaller, $\pm 0.1\,\mathrm{K}$, because it was possible to average over fairly wide spectral intervals $(60-80\,\mathrm{cm}^{-1})$ and because the IRIS signal-to-noise ratio was higher at these wavenumbers. Finally, all nightside data were corrected for a time-dependent calibration drift of the instrument. This drift occurred principally from the heating of the secondary mirror of the instrument which occurred when it became exposed to direct sunlight. The uncertainty in these calibration corrections is $<0.1\,\mathrm{K}$ at $1,304\,\mathrm{cm}^{-1}$ and $\sim0.4\,\mathrm{K}$ and $0.5\,\mathrm{K}$ at $200\,\mathrm{cm}^{-1}$ and $530\,\mathrm{cm}^{-1}$, respectively.

Results

The data have been examined for evidence of longitudinal structure. At several latitudes there were day/night observations separated by $\sim 180^\circ$ in longitude. At low latitudes longitudinal coverage was more extensive, though not complete; over limited spans of longitude, scales down to 30° could be resolved. In general fewer spectra could be averaged in this analysis than in the study of meridional structure, and the

uncertainties exceeded the formal errors quoted above. Within these uncertainties, no longitudinal or hour angle dependence of brightness temperature was discernible. Reasonable upper limits on temperature variation are 1 K at 200 cm⁻¹ and 530 cm⁻¹ and 3 K at 1,304 cm⁻¹.

Meridional variations in temperature are better defined. Table 2 summarizes all the data used. The number of spectra used in obtaining the mean brightness temperatures T_B are listed and the mean latitude and emission angle α of the data set are given. Also indicated is the emission angle correction $\Delta T_{\rm B}(\alpha)$ required to normalize $T_{\rm B}$ to $\alpha = 52.7^{\circ}$. Finally, brightness temperatures corrected for emission angle are listed. The associated uncertainties are the sum of uncertainties due to noise, emission angle corrections, and nightside calibration corrections. Because the first represents a random error while the last two are systematic, we considered the sum of their magnitudes rather than a vector sum in estimating the total error. The corrected brightness temperatures are also shown in Fig. 2. Vertical bars represent the uncertainties listed in Table 2, while horizontal bars indicate the latitude range, defined by the centres of the relevant fields of view, over which the data set comprising each point extend.

The meridional variation in brightness temperature at 200 cm⁻¹ is small. Brightness temperatures in the northern hemisphere are ~1 K higher than those at southern latitudes; a sharp transition occurs near 10° S. The meridional contrast in atmospheric temperature must also be small. The principal source of opacity at 200 cm⁻¹ has been inferred to be a system of methane clouds, situated mainly at or just below the tropopause $(\sim 100 \text{ mbar})$ and ~ 3 in total optical thickness over northern low latitudes. No configuration of clouds with these opacities could mask meridional contrasts larger than a few degrees, as the temperature lapse rate is small near the tropopause. The small difference in brightness temperature between northern and southern latitudes may be an opacity rather than a thermal effect. As the abundance of stratospheric methane is controlled by saturation just below the tropopause^{1,2}, the methane cloud system will not extend very far into the stratosphere. An increase to $\tau \sim 4$ over southern latitudes would easily account for the ~1 K brightness temperature reduction. The correlation between our data and the enhanced visual brightness in the southern hemisphere found by Smith et al.3 also suggests methane clouds. The opacity 'boundary' at ~10° S latitude seems to correlate fairly well with that discovered by Smith et al.3 within about $\pm 5^{\circ}$ of the equator.

At $530~\rm cm^{-1}$, where the effective emission level is close to the ground¹, there is a real temperature variation with latitude. Pressure-induced H_2 absorption is the major opacity source while that from clouds is relatively small, implying that the effective emission level is perhaps $\sim 1,500~\rm mbar$. The thermal variation with latitude is roughly symmetric about the equator. At low latitudes the daytime temperatures, which have smaller errors, are slightly warmer in the north than in the south. This may very well reflect a higher atmospheric opacity in the south, possibly from clouds at higher altitudes. This would be consistent with the north/south opacity difference inferred at $200~\rm cm^{-1}$. When extrapolated, the data suggest a total equator-to-pole surface temperature variation of about 3 K.

In contrast the meridional variation of the 1,304 cm⁻¹

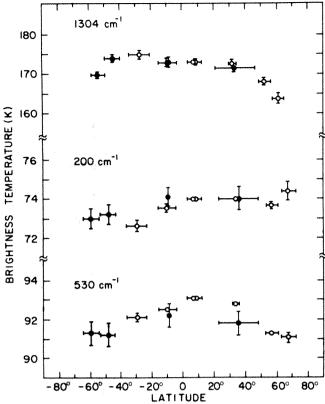

Fig. 2 1,304 cm⁻¹, 530 cm⁻¹, and 200 cm⁻¹ latitudinal distributions of brightness temperature. The 1,304 cm⁻¹ distribution is normalized to an emission angle $\alpha = 47.5^{\circ}$, while the other two are normalised to $\alpha = 52.7^{\circ}$. O, Daytime data; \bullet , night-time data. Vertical bars include uncertainties due to noise, calibration, and emission angle corrections. Horizontal bars denote the latitude range over which data comprising each point extend.

brightness temperature is much larger. Although the extrapolation is large, the poles are apparently 20 K colder than the equatorial region. There is a hemispheric asymmetry, the southern hemisphere being 3 K warmer at mid latitudes than the northern hemisphere. The structure is probably thermal in origin with little or no contribution from meridional opacity variations along constant pressure surfaces. After correcting for an emission angle of 47.5° (to which the data are normalized) the effective emission angle is less than that for the lower wavenumbers ($\alpha = 52.7^{\circ}$), because of its functional dependence on altitude in an extended spherical atmosphere. This also accounts for the slight compression of the $1,304~\rm cm^{-1}$ data along the latitude axis relative to the data at the lower wavenumbers.

Discussion

The observed thermal structure of an atmosphere represents the radiative-dynamical response to an imposed thermal driving, such as solar heating. An important measure of the inertia of an atmosphere to this driving is its radiative relaxation, or response time τ_R , (ref. 4). Smith et al.³ have estimated the radiative response time of Titan's lower troposphere to be $\sim 4 \times 10^9$ s, or 140 yr. This is much longer than a season on Titan. If $\Omega_s = 2\pi/(\text{Saturn's orbital period} = 29.5 \text{ yr})$, $\Omega_s \tau_R = 30$. Such a large value implies almost no seasonal variation in temperature. At each latitude, temperatures should respond to the annual mean insolation which is symmetric about the equator. The symmetry evident in the brightness temperatures at 530 cm⁻¹ is consistent with this.

Estimates of the radiative response time near the tropopause, to which the $200~{\rm cm}^{-1}$ brightness temperatures in Fig. 2 pertain, are not presently feasible. Most of the tropopause emission is at wavenumbers below $200~{\rm cm}^{-1}$ for which we have no data. The low meridional contrast in brightness temperature at $200~{\rm cm}^{-1}$ suggests little seasonal variation in temperature. Either the radiative time constant at the tropopause is large, $\Omega_s \tau_R \gg 1$, or the heating at this level is predominantly from absorption of

radiation emitted lower in the atmosphere where $\tau_{\rm R}$ is large and seasonal effects are small.

Radiative time constants can be estimated for Titan's stratosphere. The contribution from gaseous emission is taken into account using the formulation of Harshvardhan and Cess⁵, which assumes direct cooling to space. The cooling rate N (s⁻¹) at a pressure level P is

$$N = -\frac{\pi g}{C_p P} \Delta \nu \frac{\partial \tau_{\Delta \nu}}{\partial \ln P} \frac{\mathrm{d} B_{\nu_0}}{\mathrm{d} T} \tag{1}$$

where $\tau_{\Delta\nu}$ is the transmittance averaged over a wavenumber interval $\Delta\nu$ (cm⁻¹), B_{ν_0} is the Planck function (erg s⁻¹ cm⁻¹ sr⁻¹) at ν_0 , g is the local gravitational acceleration, T is temperature, and C_p is the specific heat. Transmittances have been obtained from a line by line spectral integration for CH₄ (ν_0 = 1,304 cm⁻¹, $\Delta\nu$ = 200 cm⁻¹), C₂H₆ (ν_0 = 820 cm⁻¹, $\Delta\nu$ = 85 cm⁻¹), and C₂H₂ (ν_0 = 729 cm⁻¹, $\Delta\nu$ = 95 cm⁻¹) (V. Kunde personal communication). Each gas was assumed to be distributed uniformly with height in the stratosphere with an abundance inferred from its observed IR emission². Radiative response times were obtained by summing over the three species (Table 3).

Radiative response times in the upper stratosphere (0.3 mbar < P < 10 mbar) are short relative to Titan's seasons but still long compared with its day. Note that the times are smaller than the preliminary estimates given by Hanel et al.². The longer radiative time constants in the lower stratosphere mainly result from the decrease in T (and hence $dB_{\rm so}/dT$) with depth in this region^{2.6}. The assumption of a uniform vertical distribution is valid only if there is rapid vertical mixing. If C_2H_6 and C_2H_2 are end products of the photo-dissociation of CH_4 at high levels of the atmosphere $(P \ll 0.1 \text{ mbar})^7$, less efficient mixing would imply that the concentrations of C_2H_6 and C_2H_2 increase with height. This would effect a decrease in response times in the upper stratosphere, and an increase at lower levels, relative to those listed in Table 3.

It has been concluded that some of the emission at 200–600 cm⁻¹ originates in the stratosphere, probably from aerosols. As the stratosphere is optically thin in this wavenumber range, the level of emission cannot be unambiguously determined. However, the deduced wavelength dependence of the aerosol emissivity is more like that expected for small particles if the emission is from the lower stratosphere ($P \sim 10-30$ mbar). If the aerosol emission is confined to a slab one scale height thick with emissivity ε_{ν} and temperature T, the radiative response time of the slab is given by

$$\tau_{\rm R}^{-1} = \frac{2\pi g}{C_{\rm p} P} \int_{200 \, {\rm cm}^{-1}}^{600 \, {\rm cm}^{-1}} \varepsilon_{\nu} \frac{{\rm d} B_{\nu}}{{\rm d} T} {\rm d} \nu \tag{2}$$

Table 3 lists τ_R at two pressure levels. The aerosol component reduces τ_R significantly below that computed for gaseous emission alone. This suggests that aerosols are the major source of cooling in the lower stratosphere.

In the upper stratosphere near 1 mbar $\Omega_s \tau_R \ll 1$, and there should be no lag in the thermal response. As only a small fraction of incident solar radiation is absorbed at higher altitudes, the meridional distribution of solar heating and temperature at solstice will be flat in the summer hemisphere, with a slight maximum at the pole, provided that the sources of thermal and solar opacity are uniformly distributed with latitude^{8,9}. The winter hemisphere will be colder with sharper gradients in temperature. At the equinoxes the temperature distribution

should be symmetric about the equator, being warmest there and coldest at the poles. The meridional distribution of the 1,304 cm⁻¹ brightness temperature at northern spring equinox (Fig. 2) roughly accords with the latter case, but the \sim 3 K hemispheric asymmetry evident at mid-latitudes is puzzling. Meridional variations in the infrared flux emitted deeper in the atmosphere where $\Omega_s \tau_R \ge 1$ cannot explain the asymmetry, as the flux is emitted at lower temperatures and does not contribute significantly to the radiative heating near 1 mbar. A hemispheric asymmetry in opacity is possible. On Earth, for example, seasonal variations in the meridional distribution of ozone account for the seasonal behaviour of stratospheric temperatures10. Although variations in aerosols and gaseous absorbers such as C₂H₂ and C₂H₆ are possible on Titan, we cannot unambiguously account for the observed asymmetry.

Figure 3 represents schematically $\Omega_s \tau_R$ with pressure level. Because of the uncertainties in the location of the stratospheric aerosol emission and in the radiative time constant at the tropopause, the transition from $\Omega_s \tau_R \ll 1$ high in the stratosphere to $\Omega_s \tau_R \gg 1$ lower down is not defined very precisely.

The meridional temperature gradients depicted in Fig. 2 imply a zonal thermal wind, u. If the surface drag is sufficiently strong, $u(z=0)\approx 0$, and

$$\frac{u^2(z)}{a}\tan \Lambda + 2\Omega \sin \Lambda \ u(z) = -\frac{1}{a} \int_0^z \frac{g}{T} \, \partial_{\Lambda} T \, dz \qquad (3)$$

where Λ is latitude, z is height, a = 2,570 km is the radius of Titan⁶, $\Omega = 4.5 \times 10^6$ s⁻¹ is its frequency of rotation, and T is atmospheric temperature. If we assume that the meridional temperature has the form $T(z, \Lambda) = T_0(z) + \Delta T(z) \cos \Lambda$ and $\Delta T = 3$ K throughout the troposphere, then at the tropopause $(z \approx 60 \text{ km}, P \approx 100 \text{ mbar})$ we infer an eastward velocity of $u \approx 36 \text{ m s}^{-1}$ at 45° latitude. This is approximately three times the surface rotational speed at Titan's equator. The larger horizontal contrasts in temperature in the stratosphere imply even stronger zonal winds. We assume that the thermal contrast between the equator and pole increases linearly with lnP from 3 K at 100 mbar to 20 K at 0.5 mbar. At 45°, equation (3) yields $u(0.5 \text{ mbar}) \approx 110 \text{ m s}^{-1}$. The estimate of the stratospheric zonal winds is uncertain insofar as we have no direct knowledge of the meridional temperature structure in the lower stratosphere. Nonetheless, it is hard to avoid the conclusion that there are global cyclostrophic flows $(u/\Omega a \gg 1)$ in Titan's atmosphere. The occurrence of such flows in the atmosphere of Venus is already well established11. However, unlike Venus, Titan has a large obliquity. The temperatures in its upper stratosphere, where $\Omega_{s}\tau_{R}$ is small compared with one, should exhibit a large seasonal variation. From equation (3), we expect a concomitant variation in the zonal winds at high altitudes.

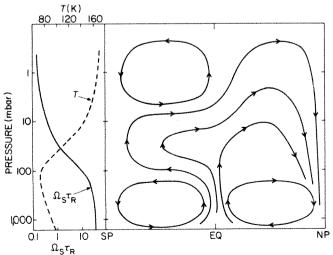

Fig. 3 Schematic diagram of the meridional flow in Titan's atmosphere at northern spring equinox. Mean vertical profiles of temperature and radiative relaxation time are indicated at the left.

Table 4 Radiative and dynamical characteristics of Titan's atmosphere

	$\frac{\Delta\theta}{(\mathbf{K})}$	D (km)	δθ (K)	$ au_{\mathbf{R}}$ (s)	V (cm s ⁻¹)	a/V (s)	(cm ² s ⁻¹)

Upper stratosphere $(P \sim 1 \text{ mbar})$	20	42	60	3×10^7	5	6×10^7	

The condition that u(0) be small compared with the zonal winds at higher levels requires that the time for surface drag to deplete the relative zonal momentum of the atmosphere be small compared with the other dynamical time scales of the problem¹². We assume a surface stress of the form $C_D u(0)^2$, where $C_D = 3 \times 10^{-3}$ is a dimensionless drag coefficient¹³. For vertical scales ($D \approx 28$ km) and zonal velocities characteristic of the lower troposphere, the surface drag time is only¹² $D/C_D u(D) \sim 10^6$ s. We will show that the meridional turnover time is much larger, $\sim 10^{10}$ s (Table 4).

The long radiative time scales in Titan's atmosphere imply that there should be no diurnal response to solar heating and this is consistent with the absence of discernible longitudinal structure in the data. The absence of this structure, however, also implies that baroclinic eddies do not have an important role in Titan's atmosphere. Previously, Leovy and Pollack¹³ concluded that baroclinic eddies are probably not effective in transporting heat on Titan. Assuming a vertical structure close to adiabatic, they found that the preferred scale of the eddies exceeded the radius of the satellite. Voyager observations, however, indicate a temperature lapse rate which is much more stable^{2,6}. This increases the preferred scale of the eddies and strengthens Leovy and Pollack's original conclusion that zonally symmetric flow constitutes the favoured mode of meridional heat transport.

Following Leovy and Pollack¹³, we consider zonally symmetric, thermodynamically direct, meridional circulations of horizontal dimension $\sim a$. There are several reasons for considering only thermally direct flows. First, the thermal contrasts forced by differential solar heating will induce a meridional transport of heat which will reduce these contrasts for the atmosphere as a whole. Second, the observed temperatures in the lower troposphere and upper stratosphere, the two regions of the atmosphere which we can treat quantitatively, are consistent with thermally direct flows. The global temperature contrasts are in the same sense as those which would obtain from purely radiative effects but reduced in magnitude. Finally, a thermally direct circulation is the simplest, and allows straightforward calculation, provided that the meridional contrasts in temperature and radiative time constants are known. Given the gaps in our knowledge of Titan's atmosphere, consideration of more complex flows is unwarranted.

We use here the Boussinesq approximation, although this limitation does not affect our conclusions. Consider an idealized meridional cell confined to altitudes z_0 and $z_0 + D$, and latitudes 0 and $\pi/2$. Let the symbol $\delta()$ denote the vertical contrast in a given quantity $(\delta(\cdot) = (\cdot)_{z=z_0+D} - (\cdot)_{z=z_0})$ averaged over latitudes $(0, \pi/2)$; Let $\Delta(\cdot)$ denote the contrast over latitude $(\Delta(\cdot) = (\cdot)^2)$ $()_{\Lambda=0}-()_{\Lambda=\pi/2})$ averaged over the depth D. The thermodynamic heat equation can be cast into the form²⁴: $\partial_t \Delta \theta + \frac{V}{a} \delta \theta \sim \frac{\Delta \theta_e - \Delta \theta}{\tau_R}$

$$\partial_t \Delta \theta + \frac{V}{a} \delta \theta \sim \frac{\Delta \theta_e - \Delta \theta}{\tau_P}$$
 (4)

where θ denotes potential temperature, and factors of the order of unity have been neglected. The term on the right-hand side represents radiative heating and cooling in terms of a linear relaxation back to the radiative equilibrium state, θ_e . The second term on the left-hand side represents the poleward transport of sensible heat and potential energy by the meridional cell. V is a mass-weighted meridional velocity averaged over the upper or lower leg of the cell. When $\Delta\theta > 0$, there is upwelling at low latitudes and poleward motion in the upper leg of the cell. The condition $\delta\theta > 0$ ensures that net transport of energy is poleward¹⁴, and the circulation acts to reduce $\Delta\theta$ ($\partial_t\Delta\theta < 0$). We will use equation (4) to estimate the magnitude of the meridional circulation at various altitudes in Titan's atmosphere.

In the troposphere $(z_0 = 0)$ the long radiative response time and absence of detectable seasonal variation imply a steady circulation, $\partial_t \equiv 0$, symmetric about the equator. As the lower troposphere contains most of the atmospheric mass, we choose D = 1.5 scale heights ≈ 28 km. Over this interval $\delta\theta \approx 22$ K (refs 2, 4). As the inclination of Titan's rotational axis to the ecliptic is presumably 27°, the annual mean insolation of the polar regions is half that at equatorial latitudes¹⁵. A crude estimate of $\Delta\theta_c$ follows from

$$\left(\frac{\theta_{\rm e}(\Lambda=0)}{\theta_{\rm e}\left(\Lambda=\frac{\pi}{2}\right)}\right)^4 \sim 2.$$

With $\theta_{\rm e}(\Lambda=0)\simeq 95$ K, $\Delta\theta_{\rm e}\approx 15$ K. The temperature contrast observed in the troposphere (Fig. 2) is much less, $\Delta\theta\sim 3$ K. With these estimates, equation (4) implies $V\sim 0.04$ cm s⁻¹, equivalent to a dynamical turnover time, a/V, $\sim 7\times 10^9$ s ~ 200 yr (Table 4).

Two potentially important transports have been neglected in this discussion of the Hadley circulation. The first is the equatorward transport by the circulation of latent heat associated with methane condensation. The second is the poleward transport of sensible heat by deep reservoirs of liquid methane which may exist on the surface of Titan. The magnitude of these transports relative to the atmospheric transport of sensible heat and potential energy is difficult to estimate. On Earth, where water is the condensate, they are all comparable, at least over those latitudes where the Hadley circulation dominates ¹⁶. In this complex situation, the net poleward transport of energy on Earth is still comparable to the atmospheric transport of sensible heat and potential energy alone. This suggests that our estimates remain correct to order of magnitude.

In the upper stratosphere the radiative response times are short. Since $\partial_t \sim \Omega_S \ll \tau_R^{-1}$, the time derivative in equation (4) can be neglected: the upper stratosphere is in radiative-dynamical balance with the current value of the seasonal forcing. For the estimate we assume a vertical scale of one scale height. At the equinoxes, radiative equilibrium implies $\Delta\theta_e \sim 10^2$ K. Using the thermal contrast $\Delta\theta \sim 20$ K inferred from the 1,304 cm⁻¹ data, we estimate $V \sim 5$ cm s⁻¹ (Table 4).

The transition from $\Omega_s \tau_R \ll 1$ in the upper stratosphere to

 $\Omega_s \tau_R \gg 1$ occurs in the lower stratosphere and tropopause region, as noted earlier. In the lower stratosphere the thermal response will lag the solar forcing; if $\Omega_s \tau_R \sim 3$ the lag is close to its asymptotic value of one season¹⁷. At the northern spring equinox, temperatures within the lower stratosphere should be warmer in the southern hemisphere than in the north. Such a thermal asymmetry would induce a pole to pole circulation with rising motion in the southern hemisphere. If such a circulation penetrated into the tropopause region, where the seasonally varying radiative heating is probably smaller, adiabatic cooling could conceivably be sufficiently strong to produce lower temperatures and enhanced condensation in the southern hemisphere, as suggested by the observations at 200 cm⁻¹. On the basis of the visible hemispheric asymmetry, Smith et al.³ suggested such a circulation for the lower troposphere. However, the magnitudes of radiative response times (Tables 3 and 4) and the global hemispheric symmetry observed at 530 cm⁻¹ (Fig. 2) suggest that such a cross equatorial circulation is more likely situated in the lower stratosphere and tropopause region.

Figure 3 illustrates one possible model of the meridional flow in Titan's troposphere and stratosphere at northern spring equinox; it assumes a uniform distribution of opacity with latitude. The topology indicated has to be speculative, because we lack sufficient information on the vertical structure of the meridional contrasts in temperature. This cannot be achieved until the vertical distribution of IR opacity is known, particularly in the lower stratosphere and troposphere. Note, however, that the vertical mass flux in the ascending leg of the meridional cell in the upper stratosphere is 0.1 that in the lower troposphere. Thus the streamlines in the stratospheric circulation possibly

close in the lower troposphere, as apparently occurs on $Earth^{18,19}$.

Although eddy transport of heat may not be important on Titan, eddies are crucial in the maintenance of its zonal momentum. The zonal velocity of $36 \,\mathrm{m\,s^{-1}}$ at 45° latitude, computed earlier, corresponds to an angular momentum per unit mass of $3\Omega a^2$. In the upper stratosphere the corresponding angular momentum per unit mass is $2\frac{1}{2}$ times larger. The angular momentum per unit mass in a zonally symmetric circulation controlled by down-gradient angular momentum fluxes is limited to Ωa^2 (refs 12, 20). Atmospheres with excess angular momentum therefore require other transport mechanisms, such as lateral mixing of vorticity or angular velocity by barotropic eddies²¹⁻²³. Upward transport of zonal momentum by vertically propagating waves is another possibility²³, although the lack of longitudinal structure in the observations precludes most conceivable planetary-scale waves on Titan.

The vertical transport of angular momentum by a zonally symmetric meridional cell must be balanced in a steady state by vertical eddy transport. The angular momentum equation, averaged over a horizontal surface from $\Lambda=0$ to $\pi/2$, is 21

$$\partial_{t} \int_{0}^{\pi/2} d\Lambda \cos \Lambda M + \int_{0}^{\pi/2} d\Lambda \cos \Lambda \partial_{z} (WM)$$

$$= \int_{0}^{\pi/2} d\Lambda \cos \Lambda \partial_{z} (\kappa \partial_{z} M)$$
(5)

In equation (5) M denotes the angular momentum per unit mass, W is vertical velocity, and κ is an eddy diffusion coefficient for vertical mixing of momentum. We have assumed the horizontal fluxes to be zero at $\Lambda=0$, $\pi/2$. Consider the lower troposphere which contains the bulk of the atmospheric mass and momentum; here the flow is steady $(\partial_{\kappa}=0)$. The requirement that there be no net exchange of angular momentum between the lower troposphere and surface implies that the vertical flux of angular momentum across a horizontal surface vanish, permitting equation (5) to be written as

$$W\Delta M \sim 2\frac{\kappa \delta M}{D} \tag{6}$$

The quantities ΔM and δM denote, respectively, the horizontal and vertical contrasts in angular momentum. An atmosphere with $\partial_z u > 0(\delta M > 0)$ requires that the equatorial angular momentum exceed that at polar latitudes $(\Delta M > 0)^{21}$. Knowing the meridional velocities from thermodynamic considerations (Table 4) permits an estimate of κ . Since $u(D) \sim \Omega a$ and $u(0) \approx 0$, in the lower atmosphere of Titan $\delta M \sim \langle M \rangle$, a tropospheric average. A Hadley cell which conserves angular momentum in its (upper) poleward branch will have $\Delta M \cong 0$. On the other hand, if eddy mixing of vorticity or angular velocity across latitudes is sufficiently vigorous, $\Delta M \sim \langle M \rangle$. Thus we expect $\Delta M/\delta M \leqslant 1$ and from equation (6)

$$\kappa \leq DW \sim \frac{D^2}{a} V \sim 10^3 \text{ cm}^2 \text{ s}^{-1}$$

From analogous considerations, Gierasch²¹ inferred a low value of vertical viscosity in the atmosphere of Venus, $\kappa \sim 10^4 \, \mathrm{cm}^{-1}$. Note that equation (6), with the added condition $\Delta M/\delta M \lesssim 1$, requires that the time for diffusion of momentum vertically through the troposphere, D^2/κ , not exceed the dynamic turnover time, a/V.

Leovy and Pollack¹³ proposed a symmetric model of Titan's tropospheric circulation and deduced meridional velocities much larger and thermal contrasts smaller than those presented here. Although their model differs from ours in several specific aspects, the most important difference lies in their treatment of internal friction. In not distinguishing between u(0) and u(D), they in effect assumed a Rayleigh friction drag in the angular momentum equation. They therefore implicitly assumed $\kappa \sim C_D u(D) D \sim 10^7 \, \text{cm}^2 \, \text{s}^{-1}$; well in excess of our derived upper limit. From equation (6) this resulted in larger meridional velocities, $V \sim 1 \, \text{m s}^{-1}$, and smaller thermal contrasts. The

anticipated seasonal variation in the zonal wind field of the stratosphere presents a more complex situation, and we will not attempt to analyse the requisite angular momentum transports.

Conclusions

IR brightness temperature at 200 cm⁻¹, 530 cm⁻¹, and 1,304 cm⁻¹ exhibit small meridional contrasts (≤3 K) in the troposphere and tropopause region and larger contrasts (~20 K) in the upper stratosphere. Radiative relaxation times estimated for the troposphere and stratosphere are large compared with the length of Titan's day. In the lower troposphere they are also large compared with the length of a season, $\Omega_s \tau_R \gg 1$, implying a lack of seasonal variation in temperature. In the upper stratosphere, $\Omega_s \tau_R \ll 1$, and seasonal variations in temperature should be large. The location of the transition region, where $\Omega_s \tau_R \approx 1$, is not well determined.

observations suggests that baroclinic waves and eddies are absent in Titan's atmosphere. Zonally symmetric flows are the

preferred mode of meridional heat transport and thermally driven planetary-scale circulations yield characteristic meridional velocities of 0.04 cm s⁻¹ in the lower troposphere and 5 cm s⁻¹ in the upper stratosphere.

The observed meridional temperature contrasts imply zonal winds which are cyclostrophic, reaching ~100 m s⁻¹ in the upper stratosphere. The anticipated seasonal variation in the stratospheric temperature field implies a concomitant variation in the zonal winds at high altitudes. The inferred cyclostrophic flow has an angular momentum per unit mass which, at least in the stratosphere, greatly exceeds Ωa^2 . In the lower troposphere, an assumed balance in the vertical transport of angular momentum by zonally symmetric meridional flow and down gradient diffusion implies a vertical viscosity of only 10³ cm² s⁻

Implications of Titan's north-south brightness asymmetry

Lawrence A. Sromovsky*, Verner E. Suomi*, James B. Pollack*, Robert J. Krauss*, Sanjay S. Limaye*, Tobias Owen*, Henry E. Revercomb* & Carl Sagan§

> * Space Science and Engineering Center, University of Wisconsin-Madison, Madison, Wisconsin 53706, USA † NASA Ames Research Center, Moffett Field, California 94035, USA ‡ Department of Earth and Space Sciences, Suny at Stony Brook, Stony Brook, New York 11790, USA § Laboratory for Planetary Studies, Cornell University, Ithaca, New York 14853, USA

Voyager 1 images of Titan, when normalized to remove limb darkening, reveal an axially symmetric brightness pattern with significant north-south asymmetry. This interhemispheric contrast seems to be a response to seasonal solar heating variations resulting from Titan's inclined spin axis. The contrast significantly lags the solar forcing, indicating that its production involves the atmosphere well below the unit optical depth level. The contrast has a significant effect on Titan's disk-integrated brightness as seen from Earth, and probably accounts for most of the observed long term variation, with solar UV variations accounting for the remainder.

EARTH-based observations^{1,2} show that between 1972 and 1976 Titan's disk-integrated brightness increased by ~9% in the blue (b) and ~5.5% in the yellow (y) to a maximum during 1976-77, and decreased through 1978. This variation and a similar but smaller variation in Neptune's brightness can be correlated with the solar cycle^{2.3}, suggesting solar variability as the common cause. As photochemical reactions are thought to produce the submicrometre aerosols in both atmospheres, we expect the variation in solar UV output during the solar cycle^{4,5} to affect the amount or physical properties of the aerosols. Pollack et al.6 showed that Titan's brightness changes during 1972-76 could be produced by changes in mean particle size, visible absorption coefficient, or optical depth, and that the fractional decrease in the particle production rate required to explain the increase in albedo was roughly consistent with the estimated fractional change in solar UV output.

A new mechanism for explaining at least part of the Earth based photometry of Titan is suggested by the Voyager 1 observations of November 1980 that showed Titan to be shrouded in an apparently unbroken cloud cover with several large-scale zonal features and a surprising north-south asymmetry in brightness7. As Titan's spin axis is inclined 27° to the ecliptic (assuming Titan is tidally locked to Saturn), the angle between Titan's axis and the line of sight to the Earth varies during Saturn's (and Titan's) 29.5-yr orbit around the Sun. The apparent tipping motion, combined with the brightness asymmetry could result in a long-term periodic variation of Titan's disk-integrated brightness. If the brightness asymmetry also varies in response to seasonal changes in solar heating of the deepest layers of the atmosphere, then the contrast would follow the seasonal heating asymmetry with a phase shift of nearly a full season and would reach an extreme value near Titan's equinoxes (near the time of the Voyager 1 encounter). Using a highly simplified model to combine the effects of the suggested seasonal changes in contrast and the time-dependent viewing conditions, the predicted brightness variation is found

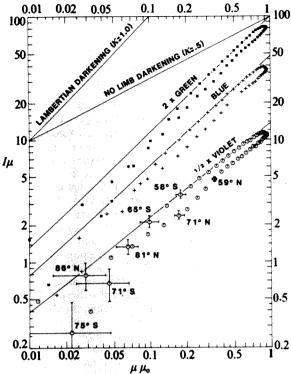

Fig. 1 Voyager 1 intensity measurements in violet, blue, and green filters, along Titan's 150° E meridian. Lines drawn for each colour show the Minnaert fits to intensities between 31° and 52° S. Intensities (in digital counts) have been corrected for dark noise but not converted to absolute units. The error bars labelled by latitude show the effects of an intensity uncertainty of ± 0.5 count and an uncertainty in μ and μ_0 corresponding to a ± 1 pixel error in the image location of Titan's centre. The identification of image line and element coordinates with Titan latitude and longitude, image navigation, is based on predicted spacecraft location and attitude information supplemented by a precise determination of camera pointing derived from the location of Titan's centre within the image.

to be in phase with the Earth-based photometry and within a factor of 2 of the observed magnitude change⁷.

The essential differences between the solar cycle and seasonal components are the driving forces and the response times. The former is driven by the changing UV output of the Sun, and brightness changes in the same direction would be expected at all latitudes at the same time, with a delay of the order of six months relative to the UV forcing function⁸. The seasonal component is driven by the tipping of Titan's axis relative to the Sun, causing simultaneous brightness changes in different directions in northern and southern hemispheres, with a time lag of nearly a full season (~7 yr). In both cases, the properties of the aerosol particles are probably modulated and in turn produce the observed brightness changes.

We now use Voyager 1 and Pioneer 11 observations, with recent Earth-based photometry, to place firmer bounds on the phase shift of Titan's contrast relative to the seasonal forcing. Describing the contrast in terms of a relative normal albedo, we calculate the time dependence of Titan's disk-integrated brightness and find a significant seasonal contribution. Finally, we use the spectral and phase angle dependence to place constraints on the mechanism which produces the contrast.

Titan's brightness contrast at the time of Voyager 1

We selected nearly simultaneous Voyager narrow angle frames in violet (0.37–0.45 $\mu m)$, blue (0.43–0.53 $\mu m)$, and green (0.52–0.60 $\mu m)$ filters (A. Collins, P. Kupferman and E. Danielson, personal communication), pictures 1305S1–003, 1289S1–003, and 1287S1–003 respectively. These were taken at 2.38× 10^6 km from Titan, at a phase angle of 29.6°, with a resolution of 44 km per line pair at the subspacecraft point. The Voyager blue and green intensities roughly correspond to Lockwood's measurements with the b filter (0.45–0.48 μm) and y filter (0.54–0.56 μm) respectively³. Relative intensities were obtained from raw digital counts by subtracting an empirically determined dark noise correction accurate to $\sim \pm 0.5$ count.

To define limb darkening characteristics each image was scanned along the 150° E meridian, using a 5×5 pixel area average stepped at $\sim3^\circ$ intervals (Fig. 1). These scans pass between the subspacecraft point at $134\,^\circ\text{E}$ and the subsolar point at 162° E, providing nearly maximal variation in scattering geometry and intensity. Figure 1 shows the dependence of intensity I (in digital counts) on μ (cosine of the observer zenith angle) and μ_0 (cosine of the solar zenith angle) as $I\mu$ versus $\mu\mu_0$ on logarithmic scales so that Minnaert scattering behaviour, for which

 $I\mu = I_0(\mu\mu_0)^k \tag{1}$

is a straight line with slope equal to the limb darkening exponent k, and intercept (at $\mu\mu_0=1$) equal to the maximum intensity I_0 . Each scan follows two nearly linear traces with similar slopes, moving along one line in the northern hemisphere and a second line, with an intercept $\sim 25\%$ greater, in the southern hemisphere. A transition occurs near the equator. Because roughly the same limb darkening slope applies over most of the latitude range for each colour, we can interpret brightness differences as differences in the intercept I_0 (proportional to the normal albedo).

We define a latitude dependent relative normal albedo (Fig. 2) as the ratio of the observed intensities to the intensities predicted from a Minnaert function fit to the 150° E scan data between 31° and 52° S for each colour. The fitted slopes are 0.773, 0.887, and 0.942 for violet, blue, and green respectively. Four major cloud zones are apparent in Fig. 2: a north mid-latitude zone between about 10° and 55° N, a north polar zone between 55° and 90° N, a south mid-latitude zone between about 20° and 60° S, and an equatorial transition zone between about 20° S and 10° N. The large variations poleward of 60° S and 80° N cannot be interpreted as true variations in normal albedo as they occur where the determination of the viewing geometry is very sensitive to navigation errors (Fig. 1) and where the Minnaert function does not accurately describe Titan's limb darkening. The normal albedo of the south mid-latitude zone is ~25% greater than that of the north mid-latitude zone, while the albedo of the north polar zone is ~7% smaller. The greatest normal albedo contrast between the south and north midlatitude zones occurs in the blue, and the smallest in the green.

The large-scale spatial structure of the normal albedo, as well as subtler cloud features are displayed as normalized images (Fig. 3) in which the intensity is proportional to relative normal albedo. The images clearly show the major cloud zones, and indicate a slightly brighter band at 45° N as identified by Smith et al.⁷. The features in the normalized images are primarily zonal (axially symmetric). The north polar zone is dark in all three colours, but darkest in violet. The bright band just south of this zone is most pronounced in the green and nearly invisible in the

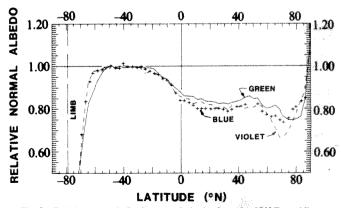

Fig. 2 Relative normal albedo versus latitude along the 150° E meridian. For each colour the relative normal albedo is obtained by dividing observed intensities by predictions based on Minnaert fits to the intensities between 31 and 52° S. The increase of normal albedo north of 70° N is not real: a decrease similar to that near 70° S is found when μ and μ_0 in the polar zone are corrected for the larger height of the clouds there. The decrease near the limb in the south is similar to that found near the limb at other latitudes and is probably a failure of the Minnaert fit to describe the true limb darkening at large viewing angles.

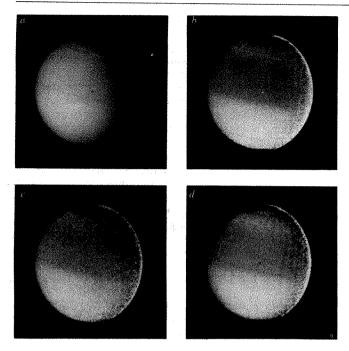

Fig. 3 Voyager 1 narrow angle images of Titan at 29.6° phase angle: unnormalized blue image (a) and normalized images in blue (b), violet (c), and green (d). In all the normalized images intensities are linear in relative normal albedo (see text) but stretched to enhance the visibility of the relatively small contrast range. A similar linear stretch has been applied to the unnormalized image (a). Its different appearance is primarily due to the presence of limb darkening. The latitude-longitude grid overlay has a 45° spacing. The equator intersects the 135° E meridian near the centre of the image (+, Titan's centre). The bright terminator in the normalized images probably results from the haze layer above the main cloud deck⁷, which could cause the observed intensities to fall off more slowly than the predicted intensities, yielding an apparent albedo increase.

violet. Minor, but definite, longitudinal variations also occur. The north polar zone boundary, for example, is slightly inclined relative to latitude lines. The green image also shows an inclined bright feature within the polar zone which may be useful as a tracer of atmospheric motions. Those small departures from axial symmetry have an insignificant effect on Titan's diskintegrated brightness and are ignored.

Phase angle dependence

We assume that the normal albedo contrast is the same at 0° phase angle (corresponding to Earth-based observing geometry) as it is at the 29.6° phase angle applicable to the Voyager 1 data shown in Figs 1–3. To test this assumption we analysed a Voyager 1 blue filter image taken at a phase angle of 9.3° (picture 1379S1–014), using the same procedures as in the analysis of the 29.6° phase angle images. No discernible change in mid-latitude contrast was found between these phase angles. The small size of the 9.3° phase angle image (30 picture elements across Titan's diameter) precludes a definitive statement about polar region changes.

Time dependence of Titan's contrast

The possible time dependence of Titan's brightness contrast can be constrained by comparing the Voyager 1 and Pioneer 11 observations (1.17 yr apart). We used a blue filtered image made by the Pioneer 11 imaging photopolarimeter (IPP) at a phase angle of 27° and at a surface resolution of ~ 170 km at the subspacecraft point (M. G. Tomasko, personal communication). The spectral range of the IPP blue filter $(0.39-0.50~\mu\text{m})$ covers both the blue and violet bands of the Voyager camera system. Because we see little spectral dependence of contrast in this spectral range, and as the albedo of Titan is higher in the blue than in the violet, we expect no significant spectral error in comparing the IPP image with the Voyager blue image.

Using the same procedures as above, a central meridian scan of the IPP image was used to define the relative normal albedo as a function of latitude. The large quantization noise in the IPP

data was reduced by averaging over two latitude belts in which the normal albedo seemed to be constant: $15^{\circ}-35^{\circ}$ S and $30^{\circ}-60^{\circ}$ N. We found a south/north normal albedo ratio of 1.26 ± 0.03 for the Pioneer measurements, compared with 1.25 ± 0.01 for Voyager. This result is consistent with either a fixed contrast or a slowly varying contrast near an extremum. We reject the former possibility because it implies brightness variations grossly inconsistent with the Earth-based photometry. The Pioneer 11/V oyager 1 comparison also suggests that the normal albedo boundary (the point at which the albedo is midway between the mid-latitude values) has moved from about 5° N to 5° S, apparently opposite to the subsolar point. But this tentative result is not included in our seasonal model calculations.

If the contrast slowly varies with a seasonal period (29.5 yr), then the direct observations by Voyager 1 and Pioneer 11 place a strong constraint on the phase shift between the solar forcing due to spin axis tipping and the contrast response. If both the forcing and the contrast response vary sinusoidally, the implied phase shift is $-84^{\circ} \pm 20^{\circ}$, where -90° corresponds to a time delay of one season, and the implied maximum south/north ratio of normal albedos is $1.26^{+0.05}_{-0.01}$. The relatively large uncertainty in phase is due to the small time interval between Voyager and Pioneer and the large quantization noise in the Pioneer results. Present results are consistent with maximum contrast near the time of the Voyager 1 encounter and allow for a large enough phase lag (near 90°) to place the contrast-induced brightness variation in phase with the Earth-based photometry.

If the normal albedo response to the solar irradiance level can be described by a single time constant, then the phase shift is determined by $\tan(\phi) = -2\pi\tau/T$, where ϕ is the phase shift. T is the orbital period of Saturn, and τ is the time constant. As $\phi \le -90^{\circ}$ is not physically possible, the time constants consistent with the phase shifts allowed by the Pioneer 11/Voyager 1 comparison fall in the range $9.6 \text{ yr} \le \tau \le \infty$, with the central phase shift of 84° corresponding to a time constant of 44.7 yr. This range of time constants is not consistent with a direct interaction between solar irradiance and aerosol properties at the unit optical depth level (at a pressure of ~1 mbar), because the thermal radiative time constant at this level and the time to reach equilibrium particle properties⁸ are both <1 yr. Large time constants can be obtained, however, if deeper levels of the atmosphere are involved in the contrast producing mechanism. For the entire atmosphere down to the 1.6-bar level a time constant of 138 yr (ref. 7) $\phi = -88^{\circ}$ is possible. A time constant of 9.6 yr only requires involvement down to the 100 mbar level.

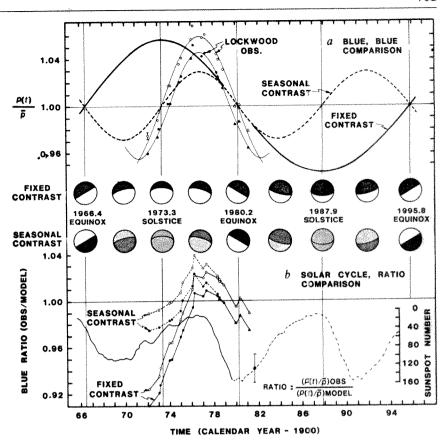

Predicted geometric albedo time dependence

We now evaluate the time dependence of Titan's diskintegrated brightness expected for two models consistent with the Pioneer 11/Voyager 1 comparison: fixed contrast and seasonal contrast with a large phase shift (-90° for this example). Because the Earth-based observations of Titan's diskintegrated brightness^{1,2} have been adjusted to fixed heliocentric distance and zero phase angle (180° scattering angle), they are proportional to Titan's geometric albedo (the ratio of diskintegrated brightness to that of a flat perfect Lambertian reflector of the same diameter). We calculate the relative geometric albedo p(t) by integrating over the illuminated hemisphere:

$$p(t) = (1/\pi) \iint a(\theta, t) [\mu_0(\theta, \theta_s(t), \phi)]^{2k} \sin(\theta) d\theta d\phi$$
 (2)

where $a(\theta, t)$ is the relative normal albedo at co-latitude θ and time t, θ_s is the co-latitude of the subsolar (and subEarth) point, and ϕ is the longitude relative to the subsolar longitude. The time dependence of the subsolar point latitude on Titan is obtained by assuming Titan's spin axis is parallel to Saturn's. We approximate the latitude dependence of the normal albedo using a 16-zone step function with boundaries spaced $\sim 10^\circ$ in latitude. Average relative albedo values for each zone are calculated for each colour from the results shown in Fig. 2. Because of the navigational and Minnaert fit uncertainties we

Fig. 4 a, Relative time variation of Titan's blue geometric albedo according to fixed contrast (heavy solid line) and seasonal contrast (heavy dashed line) models. Relative time variations derived from Lockwood's Earth-based photometry are shown for two different estimates of the mean brightness, each based on fitting an offset sine function of fixed period to the observations. One case uses the 11-yr solar cycle period; the second uses the current 13.8-vr period of the predicted seasonal brightness variation (the ellipticity of Saturn's orbit causes a deviation from the mean 14.7 period). Both fits (light lines) are good: r.m.s. deviations from the fitted curves are only about 1.5 times the estimated measurement error. Observations: ○△, relative to the mean assuming a 13.8-yr period; ● A, relative to the mean assuming an 11-yr period. Triangles indicate observations which are still preliminary. The shaded drawings illustrate the appearance of Titan at zero phase angle according to the two contrast models. The drawings exaggerate and simplify the contrast for clarity. b, Comparison of the solar cycle of smoothed sunspot number¹¹ with the ratio of observed to predicted relative variations in Titan's blue geometric albedo. Sunspot numbers are plotted along an inverted scale. The dashed portion of the sunspot curve indicates predicted behaviour based on previous cycles. The error bar indicates short term prediction uncertainty. Beyond 1983 the uncertainty is comparable with the predicted value.

assume the same albedo south of 60° S as between 52.5° S and 60° S, and ignore variations north of 85° N in finding a mean between 70° and 90° N. This normal albedo distribution is valid for 1980.9, the time of the Voyager 1 encounter. The fixed contrast model assumes the same distribution at all times. We describe possible seasonal variations in normal albedo in a simple model assuming (1) the normal albedo distribution for 1980.2 (the time of the last equinox) was the same as observed by Voyager for 1980.9, (2) the distribution for 1966.4 (time of the previous equinox) was as for 1980.2 except for a north-south reversal, and (3) at each latitude the normal albedo varied sinusoidally between the 1966.4 and 1980.2 extremes.

For fixed albedo contrast we find peak-to-peak modulation amplitudes of $\sim 10.5\%$ for violet and blue geometric albedos, and 8.2% for the green. For seasonally-varying contrast the corresponding values are 5.6% and 4.2% respectively. Figure 4a illustrates the time dependence of the geometric albedo based on the normal albedo models for the blue intensities. For fixed albedo contrast, p(t) varies in phase with the subsolar motion, reaching extreme values at the solstices. For the seasonal contrast model, p(t) attains its mean value at every equinox, when both hemispheres are equally illuminated and viewed, and at every solstice, when the interhemispheric normal albedo contrast is absent. In this case the extreme values occur midway between solstice and equinox. The shaded drawings (Fig. 4a) provide a simplified illustration of Titan's time dependent appearance according to these two contrast models.

Comparison with Earth-based photometry of Titan

The Lockwood measurements of Titan's b magnitude are plotted in Fig. 4a as relative brightnesses (brightness/time-averaged brightness). The most recent observations should be considered preliminary (G. W. Lockwood, personal communication).

The brightness variation calculated assuming a fixed normal albedo distribution is completely at odds with the Earth-based photometry. The predicted brightness is at a maximum in 1973 and beginning to decline, while the measurements are near the estimated mean value and rapidly increasing. This implies that the mean normal albedo of Titan's clouds and the relative albedo distribution with latitude cannot both be time-indepen-

dent. If the relative spatial distribution of normal albedo were fixed, then the disk-averaged mean value would have to vary dramatically to compensate as in Fig. 4b, which shows the ratio of Lockwood's blue observations to the predictions. As the ratio (for fixed contrast) changes most dramatically before 1976 when solar indicators (such as sunspot number, Fig. 4b) are changing relatively slowly, the possibility of fixed contrast and a large compensation by the solar UV mechanism seems highly unlikely.

If the relative latitudinal variation of normal albedo has the seasonal model time dependence, the predicted geometric albedo variation has roughly the same modulation period and phase as the Earth-based measurements. The assumed seasonal phase lag of 90° provides nearly optimal agreement with the Earth-based b brightness variation (Fig. 4a), although the optimal phase lag for fitting both b and y brightness curves is 82° ± 7°, where the uncertainty is based on the difference between best fit values for the two colours. The predicted peak-to-peak modulation amplitude based on the green contrast measurements is ~50-70% of the observed y brightness modulation, while the predicted blue variation is about 50-60% of the observed b brightness modulation, where the amplitude uncertainties are due to the uncertainties in Titan's mean brightness. For agreement with the Earth-based photometry the mean normal albedo can be modulated by only \sim 5% in blue and only 2.5% in the green (or y filter). This implied variation in disk-averaged mean normal albedo (Fig 4b) is roughly in phase with that expected from the solar cycle modulations of UV output (Fig. 4b), although the magnitude of the solar cycle effect in the present case would be only about half the amount suggested before Titan's brightness contrast had been discovered.

Implications of Neptune's brightness variation

The seasonal contribution to Titan's brightness variation could be significantly different from the above estimate if the boundary between high and low albedo also exhibited seasonal variation: it would be greater if the boundary moved opposite to the subsolar point motion (as suggested by Pioneer 11 measurements) and smaller if it moved in the same direction.

Thus dominance by either solar cycle or seasonal contributions remains possible. Earth-based photometry of Neptune is helpful in evaluating this possibility.

As Neptune's orbital period of 164.8 yr seems to preclude any significant seasonal changes during the 1972-80 period of the Earth-based photometry, we might expect its brightness curve to be dominated by the solar UV mechanism. The asymmetric form of Neptune's brightness variation supports this expectation: after relatively smooth increases between 1972 and 1976.5, at an average rate of 0.54% yr⁻¹ in the blue and $0.68\%\ yr^{-1}$ in the yellow, the brightness curves for both colours dropped by more than 2% in the yellow and almost 3% in the blue within the next year, with relatively little additional change from 1978 to 1980 (ref. 2 and G. Lockwood, personal communication). Thus Neptune's brightness curves are relatively well correlated with the asymmetric variation of the indicators of solar activity (Fig. 4b).

If the shape of Neptune's brightness curve represents the relative time dependence of the solar cycle contribution to Titan's brightness, then the solar cycle mechanism cannot be dominating Titan's variation. The very symmetric form of Titan's brightness curve is instead consistent with dominance by the seasonal mechanism. However, between 1972 and 1976 Titan's b magnitude increased ~70% faster than the y magnitude, while between 1976 and 1980 they both changed at about the same rate. We interpret this spectral difference as evidence for a non-seasonal component. From the amplitude of Neptune's brightness variation we infer that the solar cycle component in Titan's brightness curve would contribute ~30% of the total variation. Although one might expect a larger effect because Titan's haze layer is optically thick, while Neptune's is thought to be optically thin, a contribution much greater than 30% should produce a noticeable asymmetry in Titan's brightness curve. Thus a simple seasonal component probably accounts for more than half of Titan's secular variation, with the remainder being provided by the solar cycle mechanism.

Constraints on the contrast mechanism

As most photons reflected to space by Titan interact with the atmospheric aerosols, the hemispheric brightness asymmetry is almost certainly due to variations in their properties. The phase angle dependence of the brightness asymmetry gives an indication as to which property of the aerosols has a dominant role. Theoretical simulations with the aerosol parameters of Rages and Pollack9 indicate that the contrast declines considerably and even disappears as the phase angle decreases from 30° to 10° for a model involving variations in mean particle size, whereas little contrast alteration is expected over the same range of phase angles for models involving variations in aerosol absorption coefficient or optical depth. Thus the latter models seem to be in better agreement with the observed lack of significant contrast variation with phase angle.

The spectral dependence of the contrast also suggests that it is a reflection of differences in the sub-micrometre aerosol properties rather than differences in albedo of an underlying methane cloud layer. If the contrast was due to an albedo difference deep in the atmosphere it would be attenuated by aerosols in the upper atmosphere. However, to explain the spectral variation of Titan's geometric albedo the visible absorption coefficient of these particles must increase significantly with decreasing wavelength9. As their inferred optical depth is higher at shorter wavelengths their attenuation of the north-south contrast of an underlying cloud layer should result in significantly more contrast at long rather than short wavelengths. As this is opposite to the observed spectral variations, the contrast is more likely to be present in the properties of the sub-micrometre particles in the upper atmosphere.

The large phase shift of the contrast relative to the seasonal forcing functions shows that the contrast-producing mechanism cannot be a direct interaction between the solar irradiance and the atmosphere at the unit optical depth level. A significant depth of Titan's atmosphere must be involved to produce the time delayed response. As a relatively small north-south thermal contrast is expected at levels corresponding to large radiative time constants, a direct thermal effect on the composition or optical depth of the aerosol particles seems unlikely. The observed vertical stability of Titan's temperature profile 10 also argues against an interhemispheric difference in small-scale vertical convection as a modifying influence. This suggests that large-scale circulation asymmetries may be responsible. Possibly differences in meridional circulations, driven by an interhemispheric seasonal thermal contrast, are affecting the aerosol properties by changing the mix of trace gases available at the formation level, or by modifying their rates of removal from the formation region.

Summary and conclusions

Titan's normal albedo distribution is primarily axially symmetric with a substantial north-south contrast. As the contrast is essentially independent of phase angle it is likely to result from differences in the composition or optical depth of Titan's layer of sub-micrometre aerosols rather than differences in size distribution. The spectral variation of the contrast suggests that it is not caused by differences in the albedo of an underlying methane cloud. The contrast seems to vary with time in response to seasonal variations in solar irradiance and lags the seasonal forcing by a large phase angle, indicating that it originates probably well below the unit optical depth level. It seems to be produced indirectly, perhaps by circulation currents driven by thermal contrast at lower levels which affect the rate of removal or composition of the aerosol particles at the unit optical depth level. The contrast has a significant effect on Titan's diskintegrated brightness, and is probably responsible for most of the observed long term variation, with solar cycle effects accounting for the remainder.

There are still many uncertainties regarding the nature and origin of the contrast. A longer record of observations, both of the contrast and the disk-integrated brightness would yield a significant improvement in understanding. The nature of the contrast variation should be better defined by Voyager 2 observations in August 1981, and by the Space Telescope in the mid-1980s. If the simple seasonal model is correct we would expect the contrast to decrease to zero by the end of 1987.

Continued Earth-based photometry of both Titan and Neptune is also essential to resolve the remaining uncertainties. Between 1972 and 1978 the solar cycle component and the seasonal component have been approximately in phase, and neither has yet experienced a full cycle of variation, making their separate contributions difficult to distinguish from the brightness curves alone. The two components will become readily separated with another 5-10 years of observations as they grow increasingly out of phase, moving in opposite directions between 1981 and 1984.

We thank B. A. Smith and the Voyager imaging team for support, S. A. Collins and J. A. Anderson for help in obtaining the necessary Voyager data, G. W. Lockwood for recent brightness measurements for Titan and Neptune, M. G. Tomasko for normalized Pioneer 11 observations of Titan, and T. Wendricks for drafting the figures. This research was partially supported by JPL contract 953615.

Density waves in Saturn's rings

Jeffrey N. Cuzzi*, Jack J. Lissauer† & Frank H. Shu†

*Ames Research Center, NASA, Moffett Field, California 94035, USA †Department of Astronomy, University of California, Berkeley 94720, California, USA

Certain radial brightness variations in the outer Cassini division of Saturn's rings may be spiral density waves driven by Saturn's large moon Iapetus, in which case a value of ~ 16 g cm⁻² for the surface density is calculated in the region where the waves are seen. The kinematic viscosity in the same region is ~ 170 cm² s⁻¹ and the vertical scale height of the ring is estimated to be a maximum of ~ 40 m.

VOYAGER imaging observations of Saturn's rings¹ have revealed a wide spectrum of radial structure, indicating a variety of dynamical processes in the ring disk. Here we focus on one example of radial structure and explore its possible origin. A sequence of smoothly undulating brightness fluctuations is observed in the outer Cassini division within a band located between ~120,700 and 121,900 km from the centre of Saturn. The observed behaviour of these variations agrees with the expected behaviour of spiral density waves driven by a resonance between the apsidal motion of local ring particles and the mean motion of Saturn's outermost large satellite, Iapetus.

Basic theory

The existence of spiral density waves driven at Lindblad resonances with Saturn's major moons and propagating radially in Saturn's ring disk was suggested by Goldreich and Tremaine² as a means of transferring angular momentum over large radial distances within the disk and thereby clearing wide gaps. Similar density waves have been proposed to underlie the spiral structure of disk galaxies³. The earlier work was extended by Goldreich and Tremaine^{4,5} to the density waves that can be driven in thin disks by external and internal satellites.

Consider an axisymmetric disk of ring particles orbiting Saturn where centrifugal equilibrium at a radius r requires circular motion at angular speed $\Omega(r)$. If the particles possess small random motions in the plane of the disk (small eccentricities), Lindblad's theory of orbits⁶ allows us to think of the particles as gyrating at epicyclic frequency $\kappa(r)$ about the guiding centre of the reference circular orbit of the same specific angular momentum $r^2\Omega(r)$. Then

$$\kappa^2 = \frac{1}{r^3} \frac{\mathrm{d}}{\mathrm{d}r} (r^4 \Omega^2) \tag{1}$$

with κ^2 being equal to Ω^2 if the latter satisfies Kepler's third law: $\Omega^2 \propto r^{-3}$. For Saturn's rings, κ^2 is slightly less than Ω^2 because of the oblateness of Saturn. The small departure of κ^2 from Ω^2 is crucial to the nature of the resonant driving of the observable spiral density waves.

Suppose a moon of mass M orbits Saturn outside the rings at a mean angular speed $\Omega_{\rm M}$. Its perturbing force on the ring particles can be Fourier decomposed in time t and azimuthal angle θ (ref. 2). The mth Fourier component, having dependence proportional to $\exp[im(\Omega_{\rm M}t-\theta)]$ with m being a positive integer, will resonate with ring particle motions at a radius $r_{\rm L}$ where

$$\Omega(r_{\rm L}) - \kappa(r_{\rm L})/m = \Omega_{\rm M}. \tag{2}$$

Following the nomenclature used in galactic dynamics, we call the value r_L which satisfies equation (2) the *m*th inner Lindblad resonance of the moon M.

Ring particles slightly inside and outside $r_{\rm L}$ are induced to travel in eccentric orbits with longitude of periapse differing by π/m , leading to overlapping of their orbits. For m>1, collisions would then depopulate the overlapping orbits and clear natural gaps about the stronger resonances with fractional widths $\Delta r/r_{\rm L} \sim (M/M_{\rm S})^{1/2}$, where $M_{\rm S}$ is the mass of Saturn. Applied to Mimas's 2:1 resonance (the m=2 inner Lindblad resonance),

the above formula fails by more than two orders of magnitude to explain the observed width of the Cassini division.

To account for this discrepancy and to explain why Mimas's 2:1 resonance occurs near the inner edge of Cassini's division, Goldreich and Tremaine² invoked the self-gravity of the ring material. Consider free spiral density waves, of arbitrary wave frequency ω and azimuthal symmetry m, in a flat disk of particles which collectively behave as a fluid. Independent of their source, these waves satisfy the dispersion relation⁷:

$$(\omega - m\Omega)^2 = \kappa^2 - 2\pi G\sigma |k| + c^2 k^2 \tag{3}$$

where σ is the surface mass density, c is the one-dimensional velocity dispersion, and k is the radial wavenumber in a WKBJ analysis. Equation (3) states that the allowed square of the Doppler-shifted wave frequency equals the square of the natural frequency (the epicyclic frequency) apart from modifications required by self-gravity and acoustic effects.

From equation (3), it is easy to show that stability to axisymmetric (m = 0) disturbances of all wavenumbers requires the fluid analogue of Toomre's criterion⁸:

$$Q \equiv \frac{\kappa c}{\pi G \sigma} \ge 1 \tag{4}$$

When $Q \ge 1$, equation (3) predicts that the disk can support two types of free density waves with

$$|\mathbf{k}| = \frac{\pi G \sigma}{c^2} \left[1 \pm (1 - Q^2 D / \kappa^2)^{1/2} \right]$$
 (5)

where the upper sign corresponds to short waves and the lower to long waves, and where the departure of

$$D \equiv \kappa^2 - (\omega - m\Omega)^2 \tag{6}$$

from zero measures how far we are from exact Lindblad resonance. The value of r where

$$\omega - m\Omega(r) = -\kappa(r) \tag{7}$$

is called the inner Lindblad resonance of the wave of radian frequency ω and azimuthal mode number m. For a wave driven by an external moon of pattern speed $\omega/m = \Omega_{\rm M}$, the radial position corresponding to equation (7) is $r = r_{\rm L}$ (equation (2)).

The waves of interest here are the long waves. Near the inner Lindblad resonance of the wave, $Q^2D/\kappa^2 \ll 1$, and the dispersion relation for long waves becomes independent of c (see, for example, equation (3) for small |k|):

$$|k| = \frac{D}{2\pi G\sigma} \tag{8}$$

Equation (8) predicts that these waves formally become infinitely long at the waves' inner Lindblad resonance where D=0. Because the characteristic wavelength far from resonance, $4\pi^2G\sigma/\kappa^2(\simeq 4\pi H/Q)$ where $H\equiv c/\Omega$ is the scale height of the disk), amounts only to $\sim 10^2$ m in Saturn's rings, it is the reduction of the wavenumber |k| by the factor D/κ^2 that allows the waves at inner Lindblad resonance to be coupled to the slow spatial variation of the forcing by the external moon^{2,3}. The long waves—in particular the m=1 long waves—have the added observational advantage that they can be resolved by Voyager 1.

200

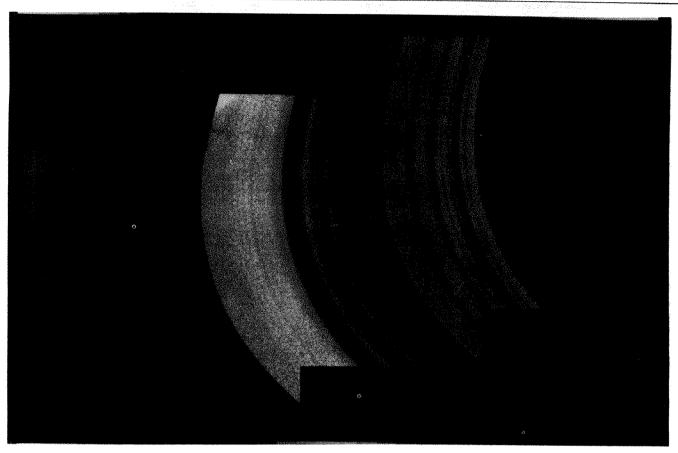

Fig. 1 A mosaic of the Cassini division of Saturn's rings, obtained from Voyager 1 observations with resolution of ~10 km per line pair (see Table 1). The region is seen from the unlit face. The prominent bright band in left centre contains a sequence of features of alternating brightness which are plotted in Fig. 2.

To understand why the m=1 inner Lindblad resonances (where the rate of apse precession of the ring particles is equal to the mean motion of the moon) are of special interest, we determine the radial range over which the waves remain significantly longer than the characteristic wavelength of 10^2 m. Because D=0 at $r=r_{\rm L}$ for driven waves, a Taylor series expansion of D about $r=r_{\rm L}$ for driven waves yields

$$D = \mathcal{D}x \tag{9}$$

where

$$\mathcal{D} = \left(r \frac{\mathrm{d}D}{\mathrm{d}r}\right)_{r_{L}} = \left(2\kappa r \frac{\mathrm{d}}{\mathrm{d}r} \left(\kappa - m\Omega\right)\right)_{r_{L}} \tag{10}$$

and $x \equiv (r - r_{\rm L})/r_{\rm L}$ is the fractional distance from Lindblad resonance. Equation (8) now implies that the radial spacing, or wavelength $\lambda = 2\pi/|k|$, between successive wave crests should be inversely proportional to the nondimensional distance x from the resonance:

$$\lambda = \frac{4\pi^2 G\sigma}{\mathcal{D}_X} \tag{11}$$

with the proportionality constant being larger for smaller values of the parameter \mathcal{D} . But in Saturn's rings, κ nearly equals Ω , so equation (10) now implies that the most readily resolved density waves correspond to m=1. Of the larger exterior moons, the only ones whose m=1 inner Lindblad resonance lies within the ring system are Iapetus, Hyperion, and Titan.

In the m=1 case, to calculate \mathcal{D} (but not to locate the resonance), it is sufficiently accurate to take

$$\kappa - m\Omega \simeq -J \left(\frac{GM_{\rm S}}{r^3}\right)^{1/2} \left(\frac{R_{\rm S}}{r}\right)^2 \tag{12}$$

where J = 0.0244 and $R_s = 60,330$ km are, respectively, Saturn's dynamical oblateness and equatorial radius. This yields for equation (10):

$$\mathcal{D} \simeq 7J\Omega_{\rm L}^2 (R_{\rm S}/r_{\rm L})^2 \tag{13}$$

Let us consider the amplitude distribution of the propagating waves whose source is m = 1 resonant driving at $r = r_L$ by an external moon. Free long waves that propagate conserving the

angular momentum luminosity F given them by a source can be shown^{2,9} to increase their fractional amplitude linearly with dimensionless distance x from the inner Lindblad resonance, $|\Delta\sigma/\sigma| = x/x_{\rm NL}$, where $x_{\rm NL}$ is the characteristic scale for waves to become nonlinear:

$$x_{\rm NL} = \frac{2\pi^2}{\mathfrak{D}} \left(\frac{r\sigma}{F}\right)^{1/2} (G\sigma)^{3/2} \tag{15}$$

For weak forcing, as occurs with Iapetus on Hyperion, $x_{\rm NL} \ge 1$, and nonlinear effects (for example, shocks¹⁰) are not important for realistic values of x. In the presence of particle collisions, however, small-amplitude density waves will suffer a viscous damping factor²

$$\exp\left[-\int_0^x k_1 r_L \, dx\right] \quad \text{where } k_1 = \frac{7}{3} \left[\frac{\kappa \mathcal{D}^2}{(2\pi G\sigma)^3}\right] \nu x^2$$

if the bulk viscosity is much less than the kinematic shear viscosity ν . Taking into account both amplitude variation factors, we obtain the wave amplitude profile near the position of the inner Lindblad resonance:

$$\frac{\Delta\sigma}{\sigma} = \left(\frac{x}{x_{\rm NI}}\right) \exp\left[-\left(\frac{x}{x_{\rm D}}\right)^3\right] \tag{16}$$

where

$$x_{\rm D} = \left(\frac{9}{7}\right)^{1/3} \frac{2\pi G\sigma}{(\kappa \nu \mathcal{D}^2 r)^{1/3}} \tag{17}$$

is the characteristic dimensionless damping length.

If spiral density waves are observed in Saturn's rings, a measurement of their wavelength yields, through equation (11), a determination of the surface mass density σ ; a measurement of the fractional amplitude variation then yields, through equations (16) and (17), a determination of the kinematic viscosity ν . Under certain assumptions, we can relate the kinematic viscosity ν to ring optical depth τ and velocity dispersion c. The vital parameters σ and ν are difficult to obtain empirically by other methods.

Table 1 Observational parame	eters of Cassini bright band
Image FDS counts used	34934.25, 34934.29
Resolution	10 km per line pair
Ring tilt angle to line of sight	74°
Normal optical depth	0.14 ± 0.02
Fit to wavelength: $\lambda(x) = A_1/(x-x_1)$	$A_1 = 0.45 \pm 0.07 \text{ km}$ $x_1 = -0.0001 \pm 0.0012$
Fit to amplitude $\frac{\Delta \sigma}{\sigma} = A_2 x e^{-(x/x_2)^3}$	$A_2 = 1.69 \pm 0.2$
-	$x_2 = 0.0115 \pm 0.001$
Theoretical amplitude $A_2 = (x_{NT})^{-1}$	1.3 (using $M/M_s = 4 \times 10^{-6}$)
Derived σ	$16 \pm 3 \mathrm{g cm^{-2}}$
Derived v	$170 \pm 80 \text{ cm}^2 \text{ s}^{-1}$

Observations and derived ring properties

During the Voyager 1 encounter with Saturn¹, several observations of the Cassini division region were obtained with spatial resolution of ~10 km per line pair (see Table 1). As viewed from the unlit face, an optically thin region of ~4,800 km width is observed between the classical A and B rings; we refer to this entire region as the Cassini division (see also ref. (11)). In the outer part of the Cassini division, at a distance from Saturn's centre of $\sim 120,700-121,900 \text{ km} \ (\pm 700 \text{ km})$ is a noticeably brighter band filled with regular, low contrast, radial brightness variations having spacings that decrease outward (see Fig. 1). Independent of the high resolution observations shown in Fig. 1, the band was observed against the bright limb of Saturn and the average normal optical depth of the band was determined as discussed by Smith et al. (see Table 1). The band appears brighter in diffuse transmission than nearby regions in the inner Cassini division because the band's optical depth is a factor of ~1.4 larger than the plateau structures in the inner Cassini division.

To obtain useful results from the very noisy data evident in Fig. 1, an azimuthal averaging technique was employed, in which data were averaged along loci of constant distance from the centre of Saturn. This method employs numerical fitting of ellipses to observed ring features at the boundaries of the region. To first order, geometrical distortion in the camera and due to the finite separation between the spacecraft and the planet is thereby removed. Typical azimuthally-averaged results, which incorporate most of the data contained in the frame, are shown in Fig. 2. The vertical brightness scale has been calibrated to reflectivity DN = I/F, in units of 10^{-4} , where I is the observed intensity and πF is the incident solar flux. The noise level of the result may be estimated from inspection of the darkest area, which is essentially empty. In particular, the mildly undulating variations located between 120,700 and 121,900 km from the centre of Saturn are real.

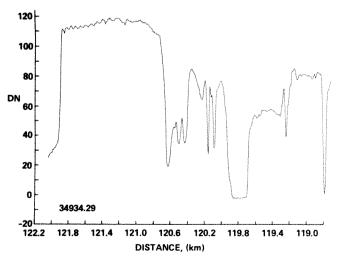

Fig. 2 Photometric scan across part of the data shown in Fig. 1. Averaging is done along lines of constant distance from Saturn, and the tracing includes most of the information contained in Fig. 1. The noise level is shown in the dark (empty) gap near 119,800 km. Radial distances shown are only accurate in an absolute sense to ±700 km or so, but relative distances are much more precisely known.

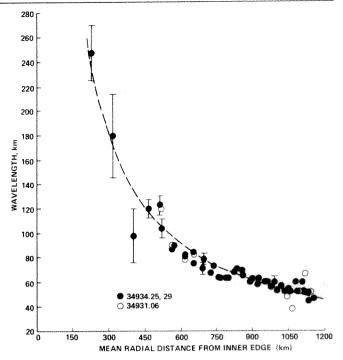

Fig. 3 Wavelength, or peak-peak/trough-trough separation, of the wave features of Figs 1 and 2 as a function of mean distance from the inner half-power point of the bright band. The best-fit curve of the form of equation (11) is shown by the dashed curve. The inverse variation of wavelength with distance is characteristic of long density waves near Lindblad resonance.

The horizontal distance scale in Fig. 2 is obtained from final spacecraft trajectory data and contains residual uncertainties of ±700 km for this observation. This uncertainty is large compared with the uncertainty <100 km to which the theoretical radial location of a given gravitational resonance may be calculated. However, relative distances are quite accurately represented in Fig. 2, and therefore, resonances can be located relative to one another once one of them has been identified.

We have calculated the predicted locations and strengths of the strongest resonances in this region of the rings following the approach of Goldreich and Tremaine⁵. The strongest resonance is the m=2 inner Lindblad resonance with Mimas. An m=1 Lindblad resonance with Iapetus lies at $2.008~R_{\rm S}$, but is several orders of magnitude weaker in torque. If we associate the Mimas 2:1 resonance with the inner edge of the Cassini division (which might entail a slight error 11), relative separations locate the Iapetus resonance at $100\pm150~{\rm km}$ outward of the inner halfpower point of the brightest band in Fig. 2. Because the undulations in brightness start near this location a more detailed investigation of the hypothesis that these undulations represent a radial slice through a tightly-wrapped spiral density-wave pattern whose source is the Iapetus resonance is necessary.

We have analysed the azimuthally averaged data obtained from two independent frames for the wavelength and amplitude behaviour of the wave pattern. For the low optical depths characterizing the region, we equate fractional brightness variations with fractional surface density variations. The fractional separations $x = (r - r_0)/r_0$ of the centroids of the peaks and troughs from an arbitrary radial location r_0 (the inner half-power point of the bright band) were measured. The peak-to-peak as well as trough-to-trough wavelengths were then plotted as functions of the distance from this arbitrary reference point. The results are shown in Fig. 3 with a best fit to the data of the form of equation (11):

 $\lambda = \frac{A_1}{r - r} \tag{18}$

where A_1 and x_1 were varied to minimize residuals. The resulting zero point offset $x_1 = -0.0001 \pm 0.0012$ implies that the source of the observed wave pattern is indistinguishable from the inner half-power point of the bright band. This is slightly inward of the theoretical location deduced on the basis of identifying the inner edge of the Cassini division with Mimas's

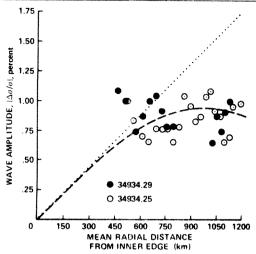

Fig. 4 Wave amplitude data (1/2 of peak-trough contrast) are plotted for the wave features of Figs 1 and 2 as a function of distance from the inner edge of the bright band. These data have been fit to a function of the form of equation (16), and the best-fit curve is shown by the dashed line. In the absence of damping, the amplitude would continue to increase linearly throughout the region instead of leveling off and then declining.

m = 2 inner Lindblad resonance, but the displacement is within the allowed uncertainties.

Comparing equations (11) and (18), we see that determination of A_1 allows us to calculate the local mass surface density σ . Our best-fit result yields $\sigma = 16 \pm 3$ g cm⁻². This is the most secure determination of a local ring property from our analysis and constitutes, to our knowledge, the only direct estimate for the ring mass density. The normal optical depth τ and surface mass density are related by

$$\tau = K\sigma \tag{19}$$

where K is the opacity, or mean cross-sectional area per unit mass of ring particles of density ρ :

$$K(r) = \frac{\int n(R, r) \pi R^2 dR}{\int n(R, r) \rho (4\pi R^3/3) dR}$$
 (20)

with n(R, r) representing the local distribution of particle radii R. Independent measurements of τ and σ yield a constraint on the ratio of integrals, K. Our analysis gives $K = \tau/\sigma \approx (9 \pm 2) \times 10^{-3} \text{ cm}^2 \text{ g}^{-1}$ for the region of interest.

For comparison, for identical particles of radius R_0 : $n(R, r) \propto$ $\delta(R - R_0)$, $K = 3/4\rho R_0$ whereas, for a power-law distribution: $n(R, r) \propto R^{-3}$ from R_1 to R_2 , as has been deduced from groundbased studies¹², $K = [3/(4\rho(R_2 - R_1))] \ln (R_2/R_1)$. Voyager radio science results¹³ for the region of our analysis indicate an effective particle radius $R_{\rm eff} \sim 8-10$ m. If this corresponded to identical particles of radius $R_0 \sim R_{\rm eff}$ and $\rho \sim 1~{\rm g~cm}^{-3}$, it would imply $K \sim 9 \times 10^{-4}$ cm² g⁻¹. In contrast, the power-law distribution, with $R_1 \sim 1$ cm (ref. 12) and $R_2 \sim R_{\text{eff}}$ (ref. 13) would predict $K \sim 6 \times 10^{-3}$ cm² g⁻¹, in much better agreement with our determination. Our analysis therefore supports a power-law distribution with an exponent of -3, although the precise value of the exponent depends on our choice for R_1 and R_2 . In particular, a steeper spectrum would allow a larger value of R_2 , possibly including many thousands of kilometre-sized bodies within the ring system¹

We now investigate whether the observed amplitude profile of the wave is consistent with the behaviour predicted by equation (16). There are two separate parameters, $x_{\rm NL}$ and $x_{\rm D}$, to be considered. First, the best-fit value for $x_{\rm NL}$ using equation (16) or the data of Fig. 2 may be compared with the expected value obtained from equation (15) using a theoretical calculation for the strength F of the Iapetus apsidal resonance and the observational determination of σ given above. Second, the best-fit for $x_{\rm D}$ using equation (16) may be used to obtain an estimate for the kinematic viscosity ν from equation (17).

The data for fractional wave amplitudes from our two pictures are shown in Fig. 4 with the minimum-residual fit for a

functional form given by equation (16). Although the data exhibit considerable scatter the waveform for density waves damped by viscosity does provide an acceptable fit to the observations. Moreover, the derived value of $x_{\rm NL}$ is within a factor of 1.3 of the theoretically expected value for wave excitation and propagation in a region of constant σ (see Table 1). This slight discrepancy may be accounted for by uncertainties in Iapetus' mass or by noting that the resonant source probably lies in a region of larger surface mass density than the region of wave propagation. Within these uncertainties, Iapetus apsidal resonance appears to contain sufficient torque to account for the observed wave amplitude.

We proceed to estimate the value of ν from our best fit for the damping length x_D . Using equation (16) and our value of σ , we obtain $\nu \sim 170$ cm² s⁻¹ (see Table 1). Although this value is less precise than our value for σ , the presence of appreciable viscosity is unquestionable given the clear departure seen in the data of Fig. 4 from an undamped linear increase of fractional wave amplitude with radial distance from the resonance.

As the waves suffer damping, the negative angular momentum they carry is absorbed by the ring particles, causing the latter to drift inward towards the inner Lindblad resonance. But this process itself does not seem to explain why the region containing the waves is a region of lower optical depth than its surroundings, as the total angular momentum transfer induced by Iapetus over the entire age of the Solar System fails by two orders of magnitude to produce the required mass removal. We believe the question of the low optical depth of the outer part of the Cassini division to be related to that of the origin and maintenance of the low optical depth of the entire Cassini division¹¹.

Under certain assumptions, the derived value of ν may be used to obtain the particle velocity dispersion c and thus the local vertical scale height $H = c/\Omega$. For instance, for particles of a single size, Goldreich and Tremaine¹⁵ have derived a form for ν which can be approximated by

$$\nu = \frac{c^2}{2\Omega} \left(\frac{\tau}{1 + \tau^2} \right) \tag{21}$$

This expression neglects gravitational focusing and scattering 16 , and is valid only if the distribution of ring particles contains few bodies with radii much in excess of 10 m. (The free fall speed onto a 10-m particle is comparable with the value of c we derive below using equation (21).) As equation (21) ignores contributions to the viscosity other than physical collisions, our determination of c based on ν yields only an upper limit. If we adopt equation (21) and set $\nu \sim 170~{\rm cm}^2~{\rm s}^{-1}$ and $\tau \sim 0.14$, we obtain $c \leq 0.6~{\rm cm~s}^{-1}$, corresponding to a ring scale height $H = c/\Omega \leq 40~{\rm m}$. From the values for σ and c, we obtain $Q \leq 30$ for the stability index, equation (4). The upper limit Q = 30 is still small enough to justify our use of the approximation $Q^2D/\kappa^2 \approx Q^2 \mathcal{D} x/\kappa^2 \ll 1$ to derive equation (8) for the region in question.

Discussion

The above results have several general implications. If ν has everywhere the same value, $170\,\mathrm{cm\,s^{-1}}$, as it does in the outer part of Cassini's division, the unconstrained spreading time $\Delta r^2/\nu$ of Saturn's rings as a whole would be comparable with the age of the Solar System. Smaller features would, of course, be much more difficult to maintain for the age of the Solar System. Indeed, unless the coefficient in the $\nu-\tau$ relation decreases rapidly with increasing optical depth (see equation (21)), ν is likely to be several times larger in the B and A rings than in the low optical depth region studied here. The persistence of even these gross features over the age of the Solar System would be called into question without another confinement mechanism.

In contrast to constant ν or c, a value for Q near its upper limit 30 everywhere would imply that the collective effects of the self-gravity of the rings are generally unimportant except very near a resonance. In the case of the m=1 waves, the waves are extremely close in frequency space to exact Lindblad resonance. In general, however, density waves become evanescent beyond

the distance from their source where equation (5) produces complex wavenumbers. This location, known in galactic dynamics as a 'Q barrier' 17, occurs in close spatial proximity to the source for all $m \neq 1$ in Saturn's rings unless Q is close to unity. For example, for density waves originating at the Mimas m=2 inner Lindblad resonance to propagate across even a continuously filled region as wide as Cassini's division, Q must be <3. If Cassini's division was cleared by such density waves Q and therefore c have to be so small that the primary contribution to the viscosity comes from gravitational scatterings by massive ring particles. In any case, our measured value of ν does require some means of maintaining the present Cassini division at a low surface density against radial diffusion by the B and A rings in a time $\Delta r^2/\nu \leq 4 \times 10^7$ yr.

The Titan apsidal resonance at a theoretical radial location of $1.288 R_{\rm S}$ is also orders of magnitude stronger in torque than the Iapetus apsidal resonance, but unlike the Mimas m=2 resonance, the Titan m=1 Lindblad resonance is free of difficulties with Q barriers, and the waves it excites should be resolvable. Yet we see no evidence, in high resolution studies, of density waves near 1.288 Rs, only a gap of a few hundred km width exists 18.

We believe that the seemingly paradoxical presence of observed density waves associated with the weak Iapetus resonance and their apparent absence from the much stronger Titan resonance has a simple explanation in the very strength of the latter resonance. It and the other strong resonances are so strong that their driven density waves become nonlinear in a short distance², $\Delta r = x_{NL}r_L$, and shock¹⁰, depositing most of their negative angular momentum in close proximity to the resonance, and thereby quite likely opening up a gap. The distance to nonlinearity for both the Mimas 2:1 resonance and the Titan apsidal resonance is 10² km, as compared with 10⁵ km for the weak Iapetus apsidal resonance. Goldreich and Tremaine² pointed out that the behaviour of the wave becomes highly uncertain after the material within $x_{NL}r_{L}$ of the resonance has been removed, and they also expressed concern in the case of the Mimas 2:1 resonance as to why the entire A ring had not been drawn into the Cassini division.

The presence of an empty region to the outside of a resonance diminishes the direct coupling of the satellite's resonant forcing to the disk on the outer side of the gap by an exponential factor if the waves must tunnel through a smoothly varying Q-barrier (edges not sharper than an inverse wavenumber). This factor in the amplitude may be roughly estimated from equation (53) of ref. 17, in the limit of small σ , as

$$\exp\left[-\frac{2}{3}\left(\frac{\mathcal{D}\Delta r}{\kappa^2 r}\right)^{1/2}\frac{\Delta r}{H}\right]$$

where Δr is the observed width of the gap. The magnitude of the exponent is >10 for the observed gap near Titan's apsidal resonance and even larger for the strong nonapsidal resonances in the rings. Thus, direct inward transport of material by strong resonances with outer moons may be self limiting. If density waves play a major part in transporting matter in Saturn's rings, it must be possible to excite waves at nonresonant positions via interactions with preexisting small-scale structure (Goldreich, personal communication).

Thus strong evidence exists in Saturn's rings for satellitedriven density waves, one in particular being driven by Iapetus at its apsidal resonance. Based on this identification, we obtain values for ring properties such as $\sigma = 16 \text{ g cm}^{-2}$; $K = \tau/\sigma =$ $9 \times 10^{-3} \text{ cm}^2 \text{ g}^{-1}$; $\nu = 170 \text{ cm}^2 \text{ s}^{-1}$; while $c \le 0.6 \text{ cm s}^{-1}$, $H \le$ 40 m, and $Q \le 30$. Firm lower bounds for c and H can be obtained by requiring axisymmetric gravitational stability when $Q \ge 1$, then our value of σ gives $c \ge 0.02$ cm s⁻¹, $H \ge 1.5$ m. Narrowing the ranges for c, H, and Q requires a careful evaluation of the relative contributions to ν by gravitational scatterings and physical collisions. This will depend critically on whether the power-law distribution of ring particles extends to bodies $>10 \, \text{m}$

Moonlets in Saturn's rings?

Jack J. Lissauer*, Frank H. Shu* & Jeffrey N. Cuzzi

*University of California, Berkeley, California 94720, USA †NASA/Ames Research Center, Moffett Field, California 94035, USA

The brightness structure within Cassini's division in Saturn's rings is explained in terms of perturbations produced by moonlets embedded within an optically thin disk of smaller ring particles. The moonlets exert gravitational torques on neighbouring ring particles and create gaps; diffusion acts to fill the gaps. A new explanation is offered for the inner edge of the Cassini division being located at the 2:1 resonance with Mimas.

VOYAGER 1 observations have revealed that Saturn's rings consist of a surprisingly large number of ringlets and narrow gaps'. Some of the features in the rings appear to be associated with resonant forcing by external moons². We have argued that some observed undulating variations of small amplitude in the outer Cassini division can be interpreted as propagating spiral density waves whose source is resonant driving by Iapetus³. However, there also exist ring structures which cannot be easily explained in terms of external gravitational perturbations.

Ring particles typically have sizes of 0.01-10 m (ref. 4), and Voyager 1 discovered several small new moons with diameters

of 30-200 km just outside the main ring system¹. Thus, we suspected the existence of bodies of intermediate size, and we investigated the idea that some of the prominent structures in Saturn's ring system might be caused by the gravitational influence of such relatively massive bodies orbiting within the ring system (see also ref. 5).

To have enough cohesive strength to survive inside the Roche limit of Saturn, the perturbing bodies must have diameters ≤100 km (ref. 6). To exert enough gravitational torque to clear gaps larger than their own sizes, the bodies must have diameters ≥2 km (see equation (14)). We refer to bodies embedded in the

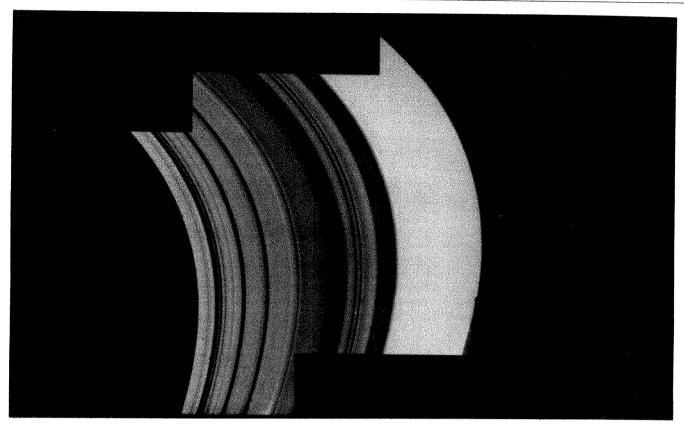

Fig. 1 Mosaic of the Cassini division in diffuse transmission. The B ring at the left and the A ring at the right appear dark because the relation, diffuse brightness proportional to optical depth, breaks down when the multiple scatterings occur. The inner Cassini division contains a series of plateaux separated by three dark narrow gaps and bounded by two dark wide rifts. The outer Cassini division (between the outer rift and the A ring) contains a faint wavelike pattern that is analysed in ref. 3.

rings which are massive enough to clear gaps larger than their own sizes as moonlets. We aim here to obtain mass estimates for unseen moonlets that may be responsible for the clearest gaps and to analyse whether such bodies could be directly detected by future spacecraft observations. We focus on the series of plateaus in the inner Cassini division which are separated by narrow gaps and set off from the B ring and the outer Cassini division by two wide gaps or 'rifts' (see Fig. 1).

Our analysis of this region follows that of ring dynamics given by Goldreich and Tremaine 7.8 and by Lin and Papaloizou 9. After the discovery of the rings of Uranus 10, Goldreich and Tremaine proposed an ingenious mechanism for creating and maintaining narrow planetary rings 11. Their mechanism invoked small unseen satellites between the rings that keep the ring particles from spreading under the influence of collisions. The discovery of two satellites 1, 1980 S26 and 1980 S27, which seem to 'shepherd' Saturn's narrow F ring supports the hypothesis.

A moonlet embedded within the ring system will exert a systematic torque on ring material located at the moonlet's outer and inner Lindblad resonances, where the ratio of the mean revolution rates of the ring Ω and of the moonlet Ω_{M} satisfy $\Omega/\Omega_{\rm M} = m/(m \pm 1)$, with m as a positive integer. The direction of this torque always acts to move ring material away from the moonlet. Collisions between ring particles broaden the resonances, and near the orbit of the moonlet, the Lindblad resonances of large m pile up and overlap. The torques can then be considered as spaced continuously over the ring material. Each moonlet thus sweeps ring material on both sides away from itself. If the moonlets are large or closely spaced, particles between the two moonlets may be pushed into quite a narrow ringlet, as is the case with the uranian rings and Saturn's Fring. Counteracting this effect, viscous diffusion tends to maintain the ringlet at a finite width. If the relative role of diffusion is increased—by an increase in the amount of material between adjacent moonlets or in the random velocities of the ring particles, by a decrease in the masses of the moonlets, or by an increase in their separation—the ringlets can spread and become plateaux wider than the gaps between them. We suggest this occurs for the prominent plateau structures in Fig. 1.

Basic equations

In a ring system where the normal optical depth τ is of the order unity, collisions between ring particles occur on time and length scales of the ring orbital period and thickness. For structures of longer duration and larger dimension, we may treat the ring material as a viscous fluid, confined to a thin sheet. Ignoring the effects of gravitational focusing and scattering 12, and assuming a single particle size, Goldreich and Tremaine 13,14 proposed a formula for the kinematic viscosity that we approximate with

$$\nu = \frac{c^2}{2\Omega} \left(\frac{\tau}{1 + \tau^2} \right) \tag{1}$$

where c is the one-dimensional velocity dispersion of ring particles. The visual optical depth τ is related to the surface mass density σ and mean cross-sectional area per unit mass of ring particles, 'opacity' K, by

$$\tau = K\sigma \tag{2}$$

In contrast, if the size distribution of embedded bodies extends from centimetres to kilometres (or larger) on a single-power law of sufficient flatness, a more important source of effective viscosity than physical collisions arises from the tendency of the larger bodies to exert torque on their neighbours in such a way as to repel the latter⁵. The same mechanism operates on all size scales, but a natural separation occurs at the size R_2 that separates bodies large enough to clear gaps around themselves (moonlets) from bodies too small to do so (ring particles). We treat the latter collection as a fluid with an effective kinematic viscosity ν given by dimensional arguments as

$$\nu = \alpha R_2 \frac{G\sigma}{\Omega} \tag{3}$$

where α is a dimensionless constant of the order of unity whose exact value depends on the exponent of the power-law that characterizes the ring-particle size-distribution.

Although equations (1) and (3) have different origins, they both give ν proportional to σ for small τ . This is the only important feature for our modelling of the inner Cassini divisions as the coefficient of proportionality between ν and τ or σ can be determined empirically. We therefore adopt equation (1) with the understanding that the quantity c should be regarded, not as the true velocity dispersion of ring particles, but merely as a parameter in the ν - τ relation. Further, we assume c to have a spatially constant value \sim 0.5 cm s⁻¹, given approximately by our determination of ν through the damping of spiral density waves in the outer Cassini division³. An equivalent procedure would have been to take $\alpha R_2 = 0.2$ km in equation (3); virtually identical results would then have been obtained in Fig. 2.

The tangential stress exerted by material outside radius r (distance from Saturn) on the material inside radius r, integrated over the thickness of the rings, is $\sigma vr \partial \Omega/\partial r$. This stress has a lever arm r and acts (in an axisymmetric system) over a circle of circumference $2\pi r$. The net torque exerted on a narrow annulus is the difference between these effects at r+dr and r; therefore, the viscous torque T_{ν} exerted per mass unit is given by 15

$$2\pi r \sigma T_{\nu} = \frac{\partial}{\partial r} \left(2\pi r r \sigma \nu r \frac{\partial \Omega}{\partial r} \right) \tag{4}$$

In the present problem, we can ignore the self-gravity of the rings and the oblateness of Saturn; we approximate $\Omega(r)$ by Kepler's third law; and equation (4) becomes

$$T_{\nu} = -\frac{3}{2r\sigma} \frac{\partial}{\partial r} (\sigma \nu r^2 \Omega) \tag{5}$$

Moonlets clear gaps around themselves by exerting torques on

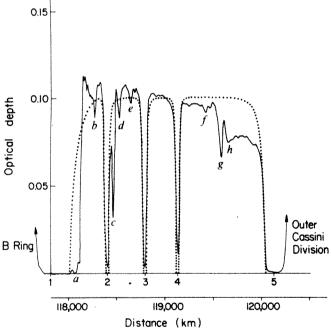

Fig. 2 Comparison of the theoretical optical depth profile with the measured diffuse transmission in the inner Cassini division. The solid curve gives the observed elliptical ring scans as a function of distance from Saturn; the dotted curve gives a theoretical fit to the data. The theoretical model adopts constant velocity dispersion, two stationary rifts moonlets, 1 and 5, and three gap moonlets, 2, 3 and 4, which have evolved to quasi-equilibrium positions. The moonlets have the properties listed in Table 1. Additional smaller moonlets may exist at positions a-h, but they were not modelled. In particular, moonlet a is required to confine the small bump (which is an optically thick narrow ring) between moonlets 1 and a, and to sharpen the inner edge of the first plateau. In these medium-resolution scans the optical depth does not reach zero at the positions 2-4, but this is an artefact as high-resolution scans show that clear gaps exist at these positions. Equilibrium solutions were also calculated for c increasing with τ . Resultant profiles have sharper gap edges, as expected from the slower diffusion rates in the lowest optical depth regions. If c decreases slowly with increasing τ , rounder edges will result. Rapid decrease of c with τ can result in diffusive instabilities20

Properties of the moonlets	
M_i/c (g cm ⁻¹ s)	$D_i (km)^*$
2.5×10^{19}	29
7.0×10^{17}	9
7.0×10^{17}	9
5.2×10 ¹⁷	8
6.9×10 ¹⁸	19
	$ 2.5 \times 10^{19} 7.0 \times 10^{17} 7.0 \times 10^{17} 5.2 \times 10^{17} $

^{*} The calculation for D_i from M_i/c assumes $\rho = 1$ g cm⁻³ and c = 0.5 cm s⁻¹.

ring particles in various kinds of resonances. If the eccentricity of a moonlet of mass M_i and radial position $r_i(t)$ is small, the torque $T_i(r, t)$ it exerts on a unit mass of fluid at radius r can be obtained from equation (18) of ref. 8, specialized to a keplerian velocity field:

$$T_{i} = 0.40 \text{ sgn} (r - r_{i}) \left[\frac{GM_{i}}{\Omega (r - r_{i})^{2}} \right]^{2}$$
 (6)

Once moonlets have emptied gaps larger than their own sizes, we may ignore accretion by and erosion of moonlets. Mass conservation of ring particles leads to the equation of continuity

$$\frac{\partial \sigma}{\partial t} + \frac{1}{r} \frac{\partial}{\partial r} (r\sigma u) = 0 \tag{7}$$

where u is the azimuthally averaged radial fluid velocity of the ring particles. Given the separate conservations of mass of ring particles and moonlets, we write the equations governing the transfer of angular momentum between the ring fluid and the J moonlets as

$$\frac{\mathbf{D}}{\mathbf{D}t}(r^2\Omega) = T_{\nu} + \sum_{i=1}^{J} T_i \tag{8}$$

$$\frac{\mathrm{d}}{\mathrm{d}t}[r_i^2\Omega(r_i)] = -\frac{1}{M_i} \int_0^\infty T_i(r,t) 2\pi r \sigma(r,t) \,\mathrm{d}r + T_i^{\mathrm{ext}}$$
 (9)

where $D/Dt \equiv \partial/\partial t + u\partial/\partial r$ is the substantial derivative and T_j^{ext} is the specific torque exerted on the jth moonlet because of possible resonant locking to a massive external moon¹⁶. In equation (8), we have assumed an absence of direct perturbations on the ring material by external moons; and in equation (9), we have ignored the possibility of resonant moonlet-moonlet interactions. The latter interactions are small for the moonlet masses and separations implied by the ring structure in Cassini's division.

In the keplerian approximation, $\partial (r^2\Omega)/\partial t = 0$ and $\partial (r^2\Omega)/\partial r = r\Omega/2$; thus, equation (8) becomes

$$\frac{1}{2}ur\Omega = T_{\nu} + \sum_{j=1}^{J} T_{j}$$
 (10)

Given c, Ω , K, M_i and T_i^{ext} , equations (1), (2), (5), (6), (7), (9) and (10) form a closed set to solve for ν , τ , T_{ν} , T_{ρ} , σ , r_i and u. We now show how quasi-equilibrium conditions simplify the solution to these equations.

Approximate equilibrium behaviour

From equations (10), (5) and (6), we readily estimate the fluid velocity u with which the jth moonlet will clear a ring gap Δr where the viscous torque has a magnitude comparable with that of the moonlet's gravitational torque:

$$ur\Omega \sim \frac{vr\Omega}{\Delta r} \sim \left[\frac{GM_i}{\Omega(\Delta r)^2}\right]^2$$
 (11)

so the characteristic time scale Δt for the gap clearing process is

$$\Delta t \sim \frac{\Delta r}{u} \sim \frac{(\Delta r)^2}{\nu} \sim \frac{(GM_i)^{4/3}}{\Omega^2 r^{2/3} \nu^{5/3}}$$
 (12)

which, with typical ring properties³, is of the order of several years for a moonlet of 2 km diameter, and scales as the moonlet diameter to the fourth power. Therefore, moonlets randomly placed among ring fluid will clear gaps around themselves in a time short in comparison with the age of the Solar System. The

ring particles must quickly move to accommodate a near balance between the torques on the right-hand side of equation (10). Approximating the spatial variation of c, Ω , r and K to be small in comparison with the resulting distribution of τ , we may set the right-hand side of equation (10) to zero and obtain

$$\frac{\tau}{1+\tau^2} + \arctan(\tau) = -\frac{0.18}{r\Omega^2} \sum_{j=1}^{J} \frac{(GM_j/c)^2}{|r-r_j|^3} + C_0$$
 (13)

where C_0 is a dimensionless integration constant. For ring material far from any moonlets, $C_0 = \tau_0/(1+\tau_0^2) + \arctan(\tau_0)$, and equation (13) predicts an optical depth profile which takes the form of a plateau $(\tau = \tau_0)$, with a steep decline as r approaches the position of the nearest moonlet on either side of the plateau. The edge of the gap, $\tau = 0$, is reached at a value of r where the right-hand side of equation (13) is zero. Equation (13) is not valid beyond this point.

For given local disk properties, there is a minimum size of a body which can lead to a clear gap. This minimum moonlet size is found by requiring that the equilibrium gap width exceed the size of the body embedded within the gap. With a spherical moonlet of internal density ρ , from equation (13) the criterion for the diameter D of a moonlet is

$$D \ge 1.4(C_0 r)^{1/3} \left(\frac{\Omega c}{G\rho}\right)^{2/3}$$
 (14)

where C_0 is a monotonic function of the plateau optical depth τ_0 . For small τ_0 , as in Cassini's division, C_0 is of the order of $2\tau_0$. With values which apply to Cassini's division today³, equation (14) implies that D must exceed roughly 2 km.

If an unconstrained moonlet $(T_i^{\text{ext}} = 0)$ were to find itself between two plateaus of different τ_0 (and therefore σ), the right-hand side of equation (9) will have a sign that forces this moonlet to move away from the high-density plateau towards the low-density plateau. The high-density plateau then spreads by viscous diffusion while the low-density plateau is compressed by the approaching moonlet. This reduces the density difference $\Delta \sigma$ between the two plateaus. When $\Delta \sigma$ has been reduced sufficiently and the evolving gap has developed enough width, the motion of the moonlet will be quite slow in comparison with the time required to produce the quasi-equilibrium ring profile given by equation (13) for fixed moonlet positions.

This suggests a simple procedure for computing the slow phase of the evolution of Saturn's ring system (most of the age of the Solar System). We calculate the moonlets' radial velocities by substituting the fluid distribution between adjacent moonlets implied by equation (13) into equation (9). New quasi-equilibrium fluid distributions can then be calculated from equation (13) after the moonlets are moved, keeping the amount of ring material constant between each pair of moonlets (Fig. 2).

Unless the boundaries of (part of) the disk are constrained by external effects (for example, moonlets locked to heavy exterior moons), no true equilibrium is possible for the ring system. (A monolayer with c = 0 and $\sigma \neq 0$ would not spread, but it would be unstable to collective gravitational disturbances.) If the inner and outer boundaries correspond to moonlets, there will be no rings to either side, and unbalanced torques in equation (9) will force these moonlets to move away from the middle. Similarly, if the inner and outer boundaries correspond to ring fluid, there will be no moonlet torques to keep the ring particles from spreading past the old boundaries. In either case, the radial spreading of the entire ring system would provide the ultimate release of orbital energy needed to sustain a non-zero level of random velocities¹⁸. In contrast, if embedded and/or boundary moonlets are constrained by resonant locking to outer moons, the maintenance of random velocities can come ultimately at the expense of a very small change in orbital characteristics of the heavy moon¹⁹. This may invalidate upper limit estimates of c based on lifetimes of Saturn's rings against viscous diffusion¹

These general comments may bear on the question of the maintenance of Cassini's division. Currently, Cassini's division and B ring material give a net outward push on the proposed moonlet ('guardian') embedded within the inner rift with a torque per unit mass which can be obtained by substituting $T_i \approx -T_{\nu}$, with T_{ν} given by equation (5), into the integral on the right-hand side of equation (9):

$$\frac{\mathrm{d}}{\mathrm{d}t} \{r_i^2 \Omega(r_i)\} = -\frac{3\pi}{M_i} [\sigma \nu r^2 \Omega]_{\mathrm{B ring}}^{\mathrm{Cassini \ division}} + T_i^{\mathrm{ext}}$$
 (15)

where the quantity in the brackets is to be evaluated well inside the Cassini division and the B ring. If the guardian is unconstrained, it could not prevent the closing of the Cassini division until the ring material reached surface densities comparable with the B ring and could exert an equal but opposite torque to balance that of the B ring. We believe that this compression is prevented by locking of the guardian in the classical 2:1 resonance with Mimas, which is itself locked to Tethys¹⁹. Using estimates of the guardian moonlet's mass, the viscosity and surface density of the B ring, we find that the Mimas 2:1 lock may barely have enough strength T_i^{ext} to keep the guardian in place. (Relevant formulae can be found in ref. (17).) Unfortunately, the proposed lock feeds eccentricity into Mimas' orbit, and unless there is a means to damp the eccentricity growth, the small current value of Mimas' eccentricity could pose a severe difficulty for this proposed mechanism.

The outer rift moonlet lies between two regions of roughly equal surface density; therefore it may remain stationary even if it is not locked to a heavy outer moon. (Note that the outer rift is located within current uncertainties at the 5:4 resonance with 1980 S27.) The outer edge of Cassini's division is a mystery. It is unlikely that a moonlet maintains the sharp density discontinuity between the division and the A ring. First, no gap is observed here down to the resolution limit of 10 km, so any moonlet present would have to be quite small. Second, the strongest resonance in this region, the 5:4 resonance with 1980 S26, has neither the right sign (for stability) nor sufficient magnitude to hold a small moonlet against the inward push of the A ring.

Independently of the mechanisms operating beyond the rift moonlets, we may use the observed locations of the gaps to fix the moonlet positions r_i at the present epoch. We can then adjust the moonlet masses and the amount of ring matter between pairs of moonlets (M_i/c) and C_0 in equation (13)) to give optical depth profiles that best resemble the major structures of the inner Cassini division. An internal check is available as the resulting structure yields, as it should, no appreciable moonlet motions if the rift guardians are held fixed. The best fit using five moonlets is given in Table 1. The resulting theoretical optical depth profile with equal heights of the plateaux (Fig. 2) is a natural consequence of the adopted physics and not of any adjustable parameter of the model. The observed approximately equal spacings of the moonlets may imply nearly uniform conditions in which the moonlets were initially formed.

Discussion

Embedded moonlets may explain why the inner rift of Cassini's division is located at the Mimas 2:1 resonance, and how large optical depth variations can be maintained between the division and the B ring. They also explain Encke's gap, which has sharp edges and no correspondence with resonances of known moons, as well as many of the gaps in the C and D rings. We conjecture that the many ringlets and grooved patterns in the B ring result from bodies massive enough to exert appreciable gravitational torques, but too small to clear resolvable empty gaps. Finally, Voyager 2 observations may detect rift moonlets if they have the sizes listed in Table 1. Gap moonlets could be harder to detect.

Distribution of neutral gas and dust near Saturn

E. C. Sittler Jr', J. D. Scudder & H. S. Bridge

* NASA/Goddard Space Flight Center, Laboratory for Extraterrestrial Physics, Greenbelt, Maryland 20771, USA † Center for Space Research, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

The distribution of neutral gas and dust within the magnetosphere of Saturn has been inferred from the electron velocity distribution functions measured by the Voyager 1 plasma science experiment. Substantial enhancements of neutral material near Titan and in the vicinity of Enceladus are found. The E ring is also shown to be larger than previously thought.

DURING the Voyager 1 encounter with Saturn, the electron plasma in the energy range 10-5,950 eV was sampled by the plasma science experiment (PLS). The electron distribution function in the vicinity of Saturn is comprised of smoothly joined thermal and suprathermal components; it is not well represented by a single gaussian distribution. We define here the location where the electron distribution departs from this typical behaviour of smooth dependence of phase space density with energy and use this to indicate the presence of neutral material in Saturn's vicinity.

We have reported that in the wake of the satellite Titan anomalous electron distribution functions were sampled by the PLS experiment. Figure 1 shows a representation of the distribution function, f(v), sampled as a function of time as Voyager passed through Titan's wake. The principal anomaly in these spectra is the 'bite-out' region above 700 eV where f(v) is abruptly reduced to values below instrumental threshold. This energy-dependent reduction should be contrasted with the smooth and otherwise regular spectra of the thermal/suprathermal type seen on either side of the bite-out feature. This 'quenching' of the suprathermal part of the spectrum has been interpreted as a result of inelastic collisions of electrons with Titan's extended neutral atmosphere. The extinction becomes strong when the electron gyroradius becomes comparable to, or greater than, the local scale height of the neutral atmosphere1. A corresponding enhancement of the low-energy population is observed, which is theoretically expected when the primary electrons become degraded and produce secondaries, and/or when the neutral gas is photoionized.

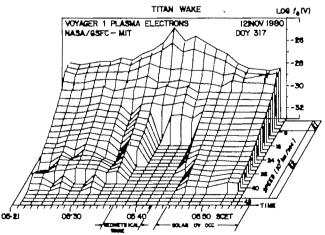

Fig. 1 The observed electron distribution functions in the Titan wake region. Energy increases towards the viewer An individual distribution is plotted at a time corresponding to measurement of its lower energy portion E1 The low and high electron energy modes of the instrument E1 and E2are indicated, respectively, where energy mode E2 is sampled 48 s after E1.

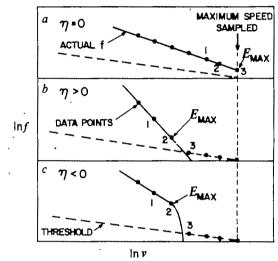

Fig. 2 Log of the distribution function plotted against the logarithm of the speed for three possible values of the curvature parameter (a, b, c). The minimum flux level or threshold and maximum speed sampled by the instrument are indicated. The data points indicated by dots represent the observed distribution function while the actual distribution function being measured by the instrument is displayed by the solid curves. The speed channel for computing $E_{\rm max}$ for each case is denoted. In computing η points 1, 2, and 3 are used. To remove any artificial scatter in η when flux levels are low, the data points 1 and 2 must be five times or more above instrument noise. If not, E_{\max} is reduced until this condition is satisfied.

We have systematically located analogous bite-out features in the distribution function samples acquired during encounter. The easiest way to quantify these features is to evaluate the curvature of the distribution function at the maximum energy (E_{max}) that the distribution is observed above the PLS instrument's flux threshold. Here we evaluate a dimensionless curvature indicator, η , given by

$$\eta = \frac{\mathrm{d}^2 \ln f(v)}{\mathrm{d} (\ln v)^2} \bigg|_{H_{-}}$$

the second derivative of the logarithm of the observed distribution with respect to the logarithm of the speed, centred at the last energy channel E_{max} which has detectable fluxes above the instrument noise and telemetry thresholds; η vanishes when the local spectrum near E_{max} is a power law in particle speed. This is usual in the magnetosphere in our energy range. Further, the curvature index has been constructed to differentiate between an intrinsic spectral change near threshold ($\eta < 0$) and a spectrum-preserving reduction in the particle flux $(n \ge 0)$.

Figure 2 shows three possible transitions of the observed speed distribution from above to below instrument threshold. A power law is assumed for the distribution function f(v) where different spectral slopes in Fig. 2a, b, c are used only for illustration. In Fig. 2a the spectrum remains above threshold for the

full energy range of the instrument: here $\eta = 0$. Figure 2b illustrates the situation where there is a spectral preserving reduction in the actual distribution function; here, because of the instrument threshold level, $\eta > 0$. Figure 2c illustrates the negative curvature situation, similar to that shown in Fig. 1 for Titan's wake. Here the spectral trend below $E_{\rm max}$ is shallower than the trend suggested by the fluxes above $E_{\rm max}$. Because the threshold level is greater than or equal to the incident particle flux above E_{\max} , an upper limit for η is determined using the threshold value as the third point in the numerical evaluation of the second derivative. The curvature parameter computed near threshold gives a qualitative measure of the curvature in f(v) at E_{max} ; and is used to identify regions where bite-out features are present and to give general trends about the energy dependence of the reduction experienced by the suprathermal electrons. Hence $\eta \ge 0$ indicates no bite-out signature, whereas $\eta < 0$ signifies a bite-out. The more negative the curvature parameter the greater the reduction in f(v).

Observations

We have processed all available electron data acquired close to and inside Saturn's magnetosphere. The results are shown in Fig. 3 with abscissa the equatorial radius, ρ , of the observer in a cylindrical coordinate system with its z axis aligned with Saturn's rotation axis. Within the plot of the L shell parameter the annotated arrows show the equatorial distance, ρ , of field lines which simultaneously thread the spacecraft and various inner satellites according to a model of the magnetic field which incorporates both an intrinsic potential model of Saturn's magnetic field and the first-order effects of a distributed ring current outside $8.7~R_{\rm S}$ (Saturn radii)³. Positions of the bow shock and magnetopause crossings¹ are also indicated, so changes in electron distribution function can be discussed in relation to the boundaries of the magnetospheric system. Note that the density scale is different for inbound and outbound passes.

In the magnetosphere the curvature parameter is usually near zero whenever E_{max} is at the upper speed channel of the instrument; this supports our interpretation that the parent distribution for the suprathermal electrons is a power law within Saturn's magnetosphere. However, in many places the η -curvature parameter is noticeably and significantly negative. The bite-out signature displayed in the three-dimensional plot of the Titan feature is retrieved as indicated by the sharp reduction in $E_{\rm max}$ and the accompanying increase in the magnitude of the negative curvature. On either side of the principal Titan feature, at least two and possibly more subsidiary density enhancements previously called 'plumes' comprised of electrons cooler than the surrounding magnetospheric electrons can be seen (19.1 and 21 R_s). These density enhancements are associated with changes in the curvature index to more negative values, but at larger values of $E_{\rm max}$ than that at Titan's wake. According to the 'plume' model¹, the density enhancement at $21 R_s$ should be of most recent origin, because it has a higher density and colder temperature, presumably due to recent contact with the Titan atmosphere. Note that E_{max} for this plume is smaller than that for the other plume seen at $19 R_s$, which should be older. In addition to these relatively clear instances of remnants of neutral plasma interactions, there is evidence for bite-out signatures in the suprathermal electrons outside of Titan's orbit all the way to the magnetopause boundary and possibly even into the magnetosheath. Centrifugal forces resulting from co-rotation would tend to move plasma which has interacted with Titan towards the magnetopause. Bite-out signatures observed in the magnetosheath could therefore result from an open magnetic topology, where the suprathermal electrons, which have encountered Titan in the past, have leaked out of the magnetosphere into the magnetosheath. Note that the intrinsic magnetosheath electron spectrum may not be a true power law, but rather maxwellian, in which case the normal curvature of the distribution function crossing the instrument threshold would be

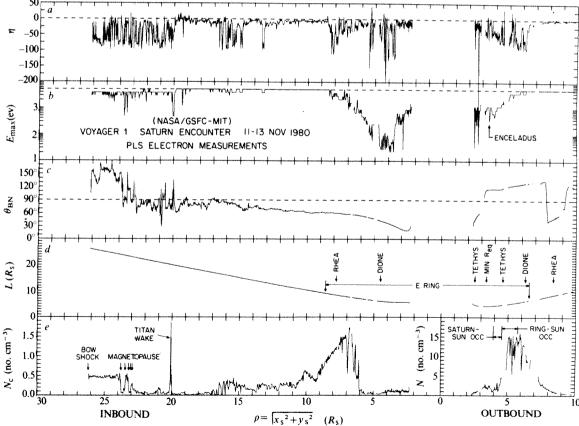

Fig. 3 Plots of spacecraft equatorial radius, ρ , against: a, η : b, maximum energy E_{\max} for which electron fluxes are observed above instrument threshold; c, angle $\theta_{\rm BN}$ between sensor look direction and current magnetic field direction 2 ; d, the dipole L shell parameter of the spacecraft; e, the electron density for the thermal electrons (low energy component). The Saturn–Sun occultation and ring–sun occultation periods are indicated. The density estimates for these periods show the trend of the data. Complications in estimating the spacecraft floating potential when solar occultation occurs means the analysis is incomplete. Any variations in the density during this period could be artificially produced by unaccounted for variations in the spacecraft floating potential and should be ignored. The spacecraft positions are computed using the Connerney $et\ al.$ model³ and not from the dipole L shell parameter.

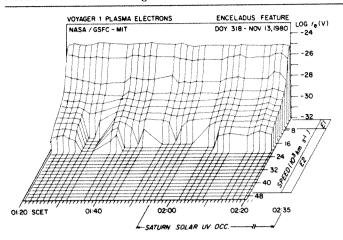

Fig. 4 Plot of the observed electron distribution function for the bite-out event observed near closest approach with Enceladus's L shell (see Fig. 1). When the spacecraft is in shadow, it may reach negative potentials of -10 V significantly below the E_{max} energies reported here. Therefore, only minor trajectory perturbations can be induced by these size potentials for electrons with energies near E_{max} . Hence little effect on the intrinsic bite-out signature is expected when the spacecraft goes into shadow in this region. Data gaps that are \sim 5 min are centred at 01:36, 01:48, 02:02, and 02:11.

negative. If true, negative curvature signatures for η in the magnetosheath may not be signatures of a bite-out.

Inside Titan's orbit on the inbound traversal between 15 and 17 R_s and briefly at 13.4 R_s there are additional intervals of large negative curvature signatures. In these intervals there is no known satellite or suggested ring or dusty material. We have considered the possibility that when Titan is near local midnight, magnetic field lines which have had close encounters with Titan could map into these smaller radial distances at local noontime. The solar wind compresses Saturn's magnetosphere at noon local time moving field lines in closer to Saturn, and distends them at midnight local time moving the field lines out to greater radial distances. The bite-out signatures inside Titan's orbit at noon local time may then be vestiges of plasma that have experienced a close encounter with Titan near midnight local time. The magnetopause of Saturn has been observed^{4.3} as 17.3 Rs to Saturn by Pioneer 11 which supports this interpretation. This interpretation also requires a persistence (lifetime) of the curvature signature over a period that is comparable to one-half the orbital period of Titan (8 days or 18 Saturn rotation periods). Losses from these field lines would be smaller than those loaded with plasma by Titan at local noon, as the latter field lines should come much closer to the magnetopause surface, and be extended further down the tail at local midnight where the field lines can open up and lose plasma^{6,7}.

E ring signature

The curvature parameter indicates another region of suprathermal extinction between 8.4 R_s inbound (317:16:56) and about 6.7 R_s outbound (318:04:45). At the extremities of this interval the curvature parameter is suddenly sharply increased in magnitude, and while remaining negative then begins a recovery towards smaller magnitude but still negative values. The value of E_{max} also exhibits a systematic variation within this interval, decreasing as we proceed towards closest approach and then recovering on the outbound traverse. The amplitude of this variation is remarkable with a range of 6,000-30 eV. Note that the onset of the sharp inbound bite-out signature occurs while the density is still rising so the decrease in the $E_{\rm max}$ parameter cannot result from decreased fluxes without a corresponding spectral change. When the sharp bite-out commences at $8.4 R_{\rm S}$ inbound the maximum energy at which particle fluxes are observed above threshold is higher than it is in the weakest curvature parts of this interval. At the outbound termination of the bite-out period at $6.5 R_s$, a similar phenomenon is observed: the erosion of f(v) is the most severe as E_{max} rises back towards the maximum PLS energy.

We suggest these signatures are produced by the interaction of particulate matter with the local thermal plasma. We associate our observations with the optically defined E ring first imaged by Feibleman8 and whose impact on the trapped particles was theoretically predicted by Thomsen and Van Allen. Thomsen and Van Allen showed that the extinction of low energy electrons (E < 6 keV) becomes more pronounced as the particle energy is raised. This is essentially the effect we have observed in the relation between the curvature index and E_{max} . The strong energy dependence arises either because the degradation of electrons is proportional to the bounce frequency which is in turn proportional to the particle speed for particles with magnetic mirror points above or below the E ring or, when this is not the case, the collision frequency is proportional to the particle speed (geometrical cross-section).

Thomsen and Van Allen make a prediction about the angular distributions expected for particles interacting with a thin ring of dust, which has been essentially confirmed by Pioneer observations^{10,11}. Particles with equatorial pitch angles near 90° are preferentially removed as their path lengths through the ring material are larger and bounce periods shorter than those whose pitch angles are near 0°. Throughout most of the interval given by the Ering in Fig. 3, the PLS electron detector had a mean field of view including particles having 90° pitch angles. For the present energy range and the pitch angles sampled, using known ranges of optical opacities of the E ring¹² and measured diffusion coefficients within Saturn's inner magnetosphere 13, the attenuation of the speed distribution is probably exponentially dependent on the electron speed. This explains the sensitivity of the curvature index as E_{max} rises, and why a sharp definition of the outer edge of the E ring results from this analysis. The PLS definition of the E ring corresponds closely to the definition of the inner boundary of the ring current by the MAG team^{3,14} The energies of electrons used here to define the E ring are substantially below that used by the Pioneer investigations; so they are more sensitive to smaller column densities than previous studies since the stopping distances or ranges for charged particles through neutral material increase with particle energy. The extension of the E ring to these radial distances also explains why the distributed currents of the outer magnetosphere seem to stop in this vicinity. Energetic ions which have ranges or stopping distances less than that of a 6 keV electron are probably the principal current carriers of the azimuthal ring current. These current-carrying ions are then removed by the E ring which determines the inner edge of the ring current.

The radial extent of the E ring is not symmetrical about Saturn; the ring extends to nearly $L = 9.0 R_s$ in the noon hemisphere and extends to $L = 6.5 R_{\rm S}$ in the outbound traverse. A similar asymmetry has been observed^{10,15} by Pioneer 11, suggesting this is a permanent feature of the E ring plasma interaction—but no explanation is available.

Within the broad E ring region another feature occurs which is not consistent with the overall trend of the bite-out signatures of the E ring itself. Between 3.7 R_s (day 317 at 21:28 LT) inbound and nearly 2.8 R_s (day 318 at 00:34 LT) outbound there is an anomalous enhancement of the E_{max} parameter. During this interval the magnetic field vector becomes increasingly aligned with the sensor look direction. This change in the relative viewing angle could be reconciled with the observation of the field aligned portion of the theoretically expected dumbbell pitch angle distribution⁷, which is outside the field of view of the instrument during the earlier portion of the E ring measurements. Alternatively, this region could be a new particle regime, with a different set of forces and history for the observed particles. This view relies on the results of Acuña et al. 4 who report that during this anomalous period a 'non-potential' feature in the magnetic field indicates a distinct spatially localized disruption of the otherwise dipolar magnetic topology. During this period the last channel above threshold increases from 50 eV to nearly 1 keV in near coincidence with the non-potential field perturbation. This shift may represent an energization of the particles or simply an enhancement of their number density. As the magnetic anomaly requires a field-aligned current and as the high mobility of the electrons argues that they would be the principal carriers, the enhanced electron fluxes in this plasma anomaly may represent the signatures of field aligned currents. The plasma data by themselves cannot, however, determine if there is a net current flow.

Enceladus signature

For the brief interval between 01:20 and 02:10 SCET on 13 November, 1980, within the general E ring bite-out, a strong reduction in the suprathermal electrons occurred similar to that shown in Fig. 1 for the Titan wake, and signified by the sharp depression in E_{max} and the curvature parameter between 3.4 and $4 R_{\rm S}$ spacecraft equatorial distance. Figure 4 shows the distribution function for this feature. The L shell distance of the strongest depression in E_{max} centred on 01:30 SCET is 4.35 R_{S} , very near the minimum L shell of 4.34 R_s predicted by Connerney et al.³ As the dipole L parameter plot indicates, L is approximately constant in this interval and it is therefore difficult to determine the equatorial distance to be ascribed to the strongest bite-out. This distance is close to, but outside, the radial distance of Enceladus, which has been suggested by Terrile and Tokunoga¹⁶ to be the source of the E ring. Terrile and Tokunoga observed a brightening of the E ring in the vicinity of Enceladus. If this interpretation is correct, we have observed bite-out signatures on flux tubes that have traversed this enhancement of dust about Enceladus. At the energies considered here, the previous explanation of the bite-out at Titan is inappropriate because the flux tubes do not come within a gyroradius (<2 km) of Enceladus or any other satellite and the scale lengths for these features are of the order of a Saturn radius. The possibility of an interaction with a localized dense cloud of gas with neutral column densities $\sim 10^{12}$ cm⁻² cannot be ruled out by these measurements, but the lack of evidence for such a dense cloud of gas from UV observations¹⁷, makes this explanation unlikely.

Conclusions

Based on our suggestion that neutral absorbing material in the vicinity of Saturn can be sensed by studying the spectral modifications to the speed distribution of low energy electrons (E < 6 keV) we have remotely identified the neutral gas around Received 13 May; accepted 15 July 1981.

Titan which is a strong quencher of the (otherwise commonplace) suprathermal electrons. A similar feature has been used to delineate the E ring, which is considerably larger than previously thought. This results from the use of lower energy electrons as the probes of dust in the ring, as they are stopped by smaller dimension particles. In our energy range the E ring is also asymmetric in local time. The present definition of the extremities of the E ring correspond closely to the inner edge of the ring current as modelled by the MAG team, which argues indirectly that ions with ranges through matter (dust) less than that of a 6 keV electron are the prominent ring current carriers.

The progressive reduction of the suprathermal electrons with decreasing radial distance within the E ring strongly suggests that the suprathermal electrons are diffusing inwards (source must be outside of E ring), whereas outside Titan's orbit we found evidence for outwards diffusion.

The removal of the suprathermal electrons within the E ring explains the apparent collapse of the plasma sheet1. Due to extinction of the suprathermal electrons, which dominate the electron pressure outside the E ring, the mean energy of the electrons decreases by a factor of ~5. Consequently, the ability of electrons to leave the equatorial plane and pull off the ions by the polarization electric field, is reduced. The scale height of the density variation should then be smaller within the Ering regime than outside. Estimates of the scale heights within and outside the E ring assuming a composition of singly ionized nitrogen are in good agreement with those inferred by Bridge et al.

We interpret a prominent extinction feature in the vicinity of Enceladus to be the result of enhanced dust around Enceladus: this may support earlier speculations that Enceladus¹⁶ is the primary source of the E ring material.

Finally, the electron fluxes are strongly enhanced relative to the ambient conditions within the non-potential magnetic field disturbance within the E ring traversal. These combined observations suggest a localized field aligned current system with the electrons being the principal current carriers.

We acknowledge the advance availability of the magnetic field data from the Voyager magnetometer team and N. F. Ness, and magnetic coordinates provided by the magnetic modelling effort of the MAG group. We thank K. W. Ogilvie and N. F. Ness for helpful comments and M. C. Harrison and L. J. Moriarty for technical assistance.

Low-frequency plasma waves near Saturn

B. M. Pedersen*, M. G. Aubier*, & J. K. Alexander*

Observatoire de Paris, Section d'Astrophysique de Meudon, 92190 Meudon, France † Laboratory for Extraterrestrial Physics, Goddard Space Flight Center, Greenbelt, Maryland 20771, USA

Voyager planetary radio astronomy observations of low frequency emissions detected around the time of closest approach to Saturn and near the outbound ring plane crossing are presented. Near the ring plane an electron density of between 5 and 20electrons cm⁻³ at distances of $\sim 6R_S$ is estimated.

THE low-frequency plasma wave emissions presented here are reminiscent of emissions observed within the Earth's magnetosphere1 and more recently within the jovian magnetosphere^{2,3}. Their most striking feature consists of intense spiky bursts, interpreted as local electrostatic upper hybrid resonances accompanied by odd-half-harmonic cyclotron, (n + $1/2)f_{\rm g}$ waves where $f_{\rm g}$ is the electron gyrofrequency. These emissions are preceded by two distinct components at frequencies lower than the normal Saturn kilometric radiation (SKR)⁴: the first one is a polarized drifting emission between 3 and

40 kHz; the second, appearing at still lower frequencies, is unpolarized and narrow banded (1-3 kHz). By analogy with observations in the terrestrial magnetosphere, these two emissions are interpreted respectively as non-thermal continuum radiations⁵ and VLF hiss.

The characteristics of the Voyager 1 trajectory close to Saturn are shown in Fig. 1. During the inbound segment, the spacecraft crossed the saturnian equatorial plane downwards at the orbit of Titan. The planetary radio astronomy (PRA)⁶ observations during this Titan flyby will be discussed elsewhere⁷. Up to the

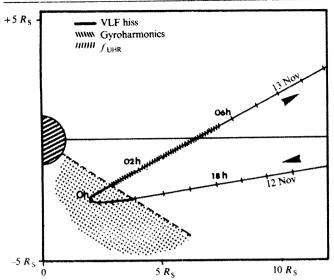

Fig. 1 A meridian plane projection of the Voyager 1 trajectory around closest approach is coded to indicate the locations where three different classes of emission are detected by the PRA experiment. From the $f_{\rm UHR}$ resonance we deduce electron densities between 5 and 20 electrons cm⁻³ (see Fig. 3). The dashed line corresponds to magnetic latitude $ML = -28^{\circ}$.

time of the closest approach, the spacecraft continued towards higher negative saturnian latitudes (also magnetic latitudes), while moving around the planet. During the outbound pass through the saturnian magnetosphere, Voyager 1 returned towards the ring plane, which it crossed at the orbit of the moon Dione $(6R_s)$ and then continued towards high positive latitudes.

The different low-frequency emissions observed near periapsis are shown as a function of time on the fixed frequency plots in Fig. 2. Each channel has a 1-kHz bandwidth, and each point represents a 6-s measurement interval. Two traces in a particular frequency channel correspond to signal levels in each of the opposite senses of circular polarization and indicate that the emission is polarized.

The emission appearing at frequencies above $\sim 60~\rm kHz$ in Fig. 2 is freely propagating SKR⁸, whereas the broad-banded emission present in all channels around the time of the outbound ring plane crossing does not show normal SKR characteristics. In particular, it does not appear at the typical saturnian longitudes for the low-frequency SKR component. We cannot explain this emission which is confined to a region around the equatorial plane. We now consider the activity which occurs only in the frequency range below $60~\rm kHz$ and which can provide information about plasma conditions in the vicinity of the spacecraft.

Impulsive emissions appear between ~1 h and 6 h in the three lowest-frequency channels. The very intense emission in the 1.2-kHz channel which saturates our receiver most of the time (intensity level $> 10^{-11} \, \text{V}^2 \, \text{m}^{-2} \, \text{Hz}^{-1}$) appears below half the local electron gyrofrequency and can be thus interpreted as VLF noise⁹. Another type of emission in this time interval consists of brief spiky bursts (Fig. 2). This impulsive emission first develops at low frequencies, moves towards high frequencies and then back to low frequencies. We interpret this pattern as a variation of the local upper hybrid resonance frequency along the spacecraft trajectory. This interpretation is supported by the resemblance to similar narrow-banded emissions observed in the magnetospheres of Earth¹ and Jupiter^{2,3}: The electrostatic noise at $f_{\text{UHR}} = (f_p^2 + f_g^2)^{1/2}$, where f_p is the local plasma frequency, allows a direct estimate of the electron density at the position of the spacecraft. The resulting density curve around closest approach is shown in Fig. 3 together with density curves estimated by Voyager 1 plasma wave (PWS)9 and plasma science experiments (PLS)¹⁰. A time discrepancy is noted with respect to PWS results, whereas our maximum density (~20 electrons cm⁻³) is only slightly higher than the PLS value.

Preceding this developing f_{UHR} line we observe smooth emission humps of longer duration on the 20.4 and 39.6 kHz

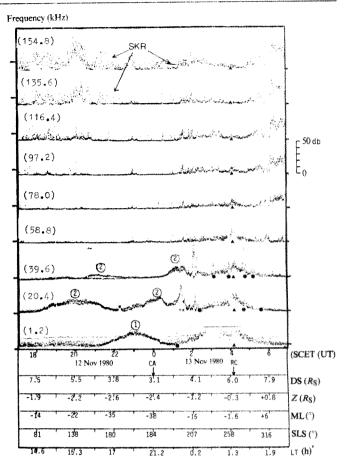

Fig. 2 Fixed frequency plots (intensity in dB μ V⁻¹ kHz⁻¹) of the lowest PRA frequencies as a function of the distance (D_s) from Saturn. The distance (Z) from the equatorial plane, the magnetic latitude (ML), the Subspacecraft Saturn Longitude (SLS) and the local time (LT) are shown. CA denotes the point of closest approach, and RC denotes the ring plane crossing. The broad-banded emission around RC (Δ), the $In + 1/2if_g$ waves (\times), the $In + 1/2if_g$ waves (\times), the VLF hiss (Ω) and escaping (Ω) continuum radiations are indicated. The intense spiky emission from 2 h to 5 h on the 1.2-kHz channel is interpreted as VLF noise. The emissions observed throughout the period at frequencies ≥ 60 kHz are due to freely propagating Saturn kilometric radiation.

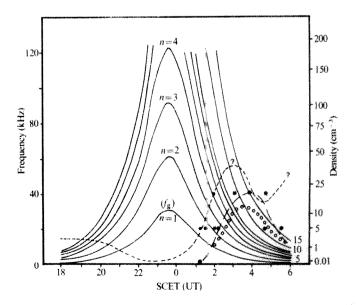

Fig. 3 Appearance of electrostatic emissions $(\times, \text{ smooth } (n+1/2)f_k$ humps; \bullet , f_{UHR} spiky resonances) with respect to the evolution of the gyroharmonic pattern as calculated from the measured magnetic field (left ordinate). The density profile deduced from the PRA observations (---) is compared with the Voyager PLS¹⁰ (200000) and PWS⁹ (----) results (right ordinate).

channels (Fig. 2). We interpret these emissions as $(n+1/2)f_n$ harmonic waves. Such waves are also observed in the vicinity of the Earth1 and within the Io plasma torus2.3 and generally accompany f_{UHR} waves. Figure 3 shows the position of these waves with respect to the gyroharmonic pattern calculated from Voyager 1 magnetic field measurements¹¹. The location of the gyroharmonic waves in relation to the f_{UHR} waves can be interpreted in terms of the relative temperatures of a twocomponent electron distribution consisting of a 'cold' background plasma and a 'hot' component that provides a source of free energy for the waves³.

In the Earth's and Jupiter's magnetosphere¹² the whole pattern of (n+1/2) f_g and f_{UHR} electrostatic waves in some cases seems to be closely associated with two components of non-thermal electromagnetic radiation: an escaping and a trapped continuum component. The emission of type 2 in Fig. 2 resembles such a non-thermal continuum: this polarized emission drifts between frequencies ≤ 20 kHz and ~40 kHz and is typical of an apparently distinct narrow-banded component of SKR that is seen intermittently in the PRA data throughout the encounter period4. Its characteristics are similar to the narrowband jovian kilometric radiation (nKOM)¹³, and both may

originate in the same physical process as the escaping non-thermal continuum radiation¹². At lower frequencies around 1 kHz a smooth, intense and unpolarized emission 1 (on Fig. 2) is observed during a short period at latitudes lower than -28° (Fig. 1). Gurnett et al⁹ interpret this low frequency component, below the plasma frequency and far below the gyrofrequency, as VLF noise.

We have shown that the different emission components of the low-frequency spectrum observed during the Saturn encounter constitute a similar pattern to the spectra observed elsewhere (see Fig. 9 of ref. 12). The combination of strong, impulsive bursts at f_{UHR} and smooth emissions at $(n+1/2)f_g$ is common in plasma populations consisting of a mixture of relatively cold and hot energetic magnetospheric plasmas. This mixture, as pointed out for the terrestrial and jovian magnetospheres by Kurth et al.12, agrees with the emission mechanism proposed by Melrose 14, according to which the non-thermal radio continua result from conversion of upper hybrid waves into electromagnetic waves by coalescence with low-frequency waves. Finally our estimate of the electon densities near the time of the outbound ring plane crossing $(4 \le R \le 7R_s)$ agrees reasonably well with the direct measurements by the PLS team 10.

Impulsive radio discharges near Saturn

David R. Evans*, James W. Warwick*, Jeffrey B. Pearce*, Thomas D. Carr* & John J. Schauble

> *Radiophysics, Inc, 1885 33rd Street, Boulder, Colorado 80301, USA †Department of Astronomy, University of Florida, Gainesville, Florida 32611, USA

An unexpected type of emission was observed during the Voyager 1 Saturn encounter. This consisted of periodic episodes of many impulsive discharges throughout the frequency range (20.4 kHz to 40.2 MHz) of the planetary radio astronomy experiment.

NON-THERMAL radio emissions from the Saturn system were first detected by the Voyager planetary radio astronomy (PRA) experiment on board Voyager 1 in January 1980. Since then emission between 100 kHz and ~1 MHz from the planet, termed Saturn kilometric radiation (SKR), has been detected almost continuously. Observations of SKR are detailed elsewhere1. For only a few days around encounter a broadband (100 kHz to at least 40 MHz) emission was observed. Initial observations of this form of emission are given elsewhere²; here we detail the further analysis of these data.

In its normal mode, the PRA receiver scans downward in frequency through 198 channels between 40 MHz and 1.2 kHz and samples each channel for 30 ms. Each scan includes experiment status information, and requires 6 s (ref. 3). Figure 1 shows part of a typical dynamic spectrum obtained by the receiver in this mode near encounter, in which several vertical streaks are apparent. We believe² that these streaks have a physical cause outside, and independent of, the spacecraft. The detailed structure of an individual streak (or 'event') can be determined only on the rare occasions that the PRA receiver is operating in its 'high rate' mode, when two preselected pairs of adjacent frequency channels are sampled simultaneously once every 140 µs. Although we only have 48 s of such data which exhibit clear events, obtained ~4 h after encounter, this is enough to examine the detailed structure of such events, which in many ways resembles the radio signature of a terrestrial lightning discharge. This, and properties previously listed², leads

us to conclude that we are observing the effects of short-lived electrostatic discharges originating in the vicinity of Saturn (hence Saturn electrostatic discharges (SED)).

To understand better the properties of SED, an algorithm was

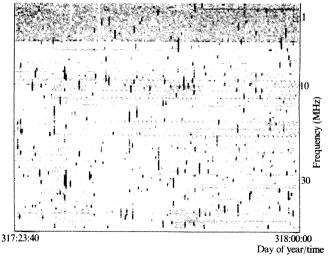

Fig. 1 Dynamic spectral scans from the PRA experiment near closest approach. The SED appear as short vertical streaks whose duration is proportional to the height of the streaks. The broadband nature of the phenomenon is clear.

written to identify and log each individual discharge event occurring in the regular low rate data. This proved to be much more sensitive than the plotting of dynamic spectra as in Fig. 1. The rate of discharge occurrence varied markedly throughout the encounter period with the SED being generally confined to apparently periodic episodes. Given the relatively limited data base, and the rapidly changing geometry of the Saturn system as seen from the spacecraft during encounter, the inherent periodicity of these episodes cannot be estimated precisely. We calculate, however, that the observed events are consistent with a source revolving about the planet with a period of ~10 h 10 min (±5 min), radiating away from the planet. The possibility of a corotating phenomenon (of period near 10 h 40 min), previously thought to be a plausible explanation of the observations, is now clearly excluded. Generally, SED episodes are observed over slightly more than 50% of this orbit, which is located about 1.81R_s (Saturn radii) from the centre of the planet. Figure 2 shows all the clearly defined episodes we observed; each frame represents one revolution of a reference frame rotating with period 10 h 10 min about the centre of Saturn (0° is defined as that longitude facing the vernal equinox of Saturn at 1.0 January 1970), with spacecraft motion taken into account. The episodic nature of the phenomenon is clear. For convenience, the episodes have been assigned identifying numbers as in Fig. 2.

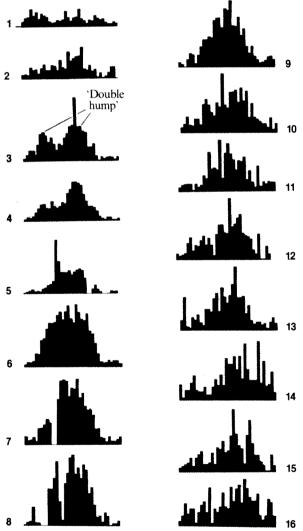

Fig. 2 The episodic gross structure of SED which shows the 16 relatively well-defined episodes (closest approach takes place during episode 5). Each episode consists of 36 bins each 10° longitude wide, representing the sub-spacecraft longitude of a system rotating about Saturn's centre once every 10 h 10 min. The length of each bar is a function of the numbers of observed SED events and the spacecraft distance from $r = 1.81R_s$. This convolution increases the relative noise background with increasing distance from $r = 1.81R_s$.

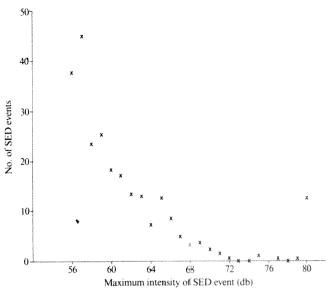

Fig. 3 Maximum intensity of SED bursts for the available high-rate data. Instrument cutoff occurs at +80 dB. The number of points at or above cutoff is highly anomalous and indicates indirectly the possibility of two distinct populations of SED.

Dynamic spectra such as Fig. 1 exhibit clearly the broadband nature of SED. Generally whilst within an episode, we observed SED in all channels which were not swamped by SKR emission. This normally limited us to frequencies ≥800 kHz. For part of the encounter episodes, however, SKR was absent at the lowest frequencies, and SED was clear even below 100 kHz. To test the broadbandedness of SED, spectra consisting of the number of SED events observed per channel on an episode-by-episode basis were calculated. At encounter (episode 5) the spectrum appears remarkably flat; what features are present are due to the sensitivity curve of the receiver, and the changing shape of the spectrum as the spacecraft moves in the days around closest approach indicates that at encounter relatively few discharges go undetected.

Note also that the onset of an SED episode is not uniformly simultaneous at all frequencies. In particular, the encounter episode was observed at 40 MHz some 4.5 h before it was seen at 10 MHz. The start of other episodes and the end of all episodes seem to be independent of frequency.

A marked feature of Fig. 2 is the asymmetry about closest approach; the earliest recognizable SED were observed only ~36 h before closest approach, whereas post-encounter episodes continued for some days. Two of the pre-encounter episodes exhibit a clearly double-humped envelope, a feature

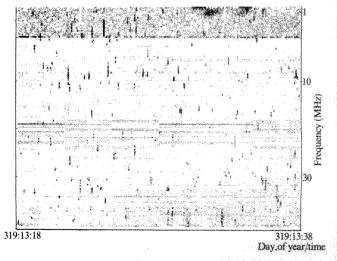

Fig. 4 Dynamic spectrum similar to Fig. 1 for episode 6. The alternating light and dark squares during many SED events indicate the presence of circular polarization, in this case overwhelmingly in the left-hand sense.

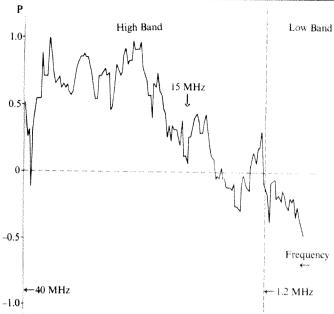

Fig. 5 Polarization as a function of frequency for post-encounter episode. Frequency runs between 40 MHz at left to ~800 kHz at right. A three-point running mean has been used to smooth the curve. Very few points were available at the top of the high band, but at other frequencies above about 15 MHz (marked with arrow) most bursts are clearly left-circularly polarized. Below 15 MHz there is little evidence for any systematic sense of polarization.

which does not appear to be present after the encounter. There is some evidence that this could be due to a smaller source of SED revolving about the planet with a longer period ($\sim 10\,h$ 30 min). Pre-encounter, the two sources are just resolved. During the period displayed in Fig. 2 the faster source catches up with, and may overtake, the slower source, and so for the strongest episodes (numbers 3–9), the two are unresolved. In support of this, the early episodes seem to have a slightly greater angular width than the later ones. Support for a two-source model comes from an investigation of the intensity characteristics of the bursts detected in the high rate mode, which exhibit results typical of the superposition of two or more populations (Fig. 3). This hypothesis cannot be rigorously checked until the Voyager 2 encounter.

In the normal mode, the PRA receiver is sensitive to circular polarization. The sense of polarization sampled alternates from channel to channel as a 6-s scan progresses. (Alternating 6-s scans start with alternating polarization sampling of the first

channel.) Consequently, should a given SED event show circular polarization, it would appear as a streak of alternating light and dark squares on a dynamic spectrum plot. A search for this phenomenon yielded many examples, such as shown in Fig. 4. We defined an index of polarization for the *i*th channel, P(i), by

$$P(i) = (L(i) - R(i))/(R(i) + L(i))$$

where R(i), L(i) are the number of 30 ms samples of right-hand and left-hand polarization of the ith channel in which an SED signal was detected. An examination of the SED on the basis of polarization showed that episodes 1–5 contained very few clearly polarized events out of many thousands. Post-encounter episodes, however, were generally strongly left-hand circularly polarized. Polarization/frequency plots were produced for each episode. Figure 5 shows the results for the first post-encounter episode. The SED are clearly strongly left-circularly polarized above ~ 15 MHz. Below this frequency, the degree of circular polarization is much less, and the sense is frequency-dependent.

We have previously citch nn on polarization as being evidence of a discharge². Despite the present finding, we still believe that we are observing electrostatic discharges, which are polarized by virtue of either magnetic or curved electric fields, and consequently we have retained the term 'SED'.

In conclusion, some eight characteristics have now been fairly well defined by the Voyager 1 encounter:

- (1) a very flat, broadband frequency spectrum;
- (2) a period of $\sim 10 \text{ h } 10 \text{ min}$;
- (3) a change in the envelope shape of episodes between preand post-encounter;
- (4) an intensity population structure typical of plural populations;
- (5) episodic structure of width ~180°;
- (6) post-encounter episodes continue for about three times as long as pre-encounter ones;
- (7) post-encounter bursts are left-circularly polarized at high frequencies;
- (8) at least one episode shows the onset of high frequency events some time before that of lower frequency ones.

Any theory for the generation of SED should account for all these characteristics.

We thank other members of the PRA team for helpful suggestions and criticisms of this work. It was supported by NASA-Jet Propulsion Laboratory.

X-ray and energetic neutral particle emission from Saturn's magnetosphere

E. Kirsch*, S. M. Krimigis†, W. H. Ip* & G. Gloeckler‡

*Max-Planck Institute for Aeronomy, D-3411 Katlenburg-Lindau 3, FRG † Applied Physics Laboratory, The Johns Hopkins University, Laurel, Maryland 20707, USA ‡ Department of Physics and Astronomy, University of Maryland, College Park, Maryland 20742, USA

Although Voyager 1 was not equipped for the detection of X-rays and neutral particles, its low energy charged particle detector (LECP) records suggest a significant flux of these radiations. X-rays could be due to substantial precipitating electron fluxes in the auroral region or the rings whereas energetic neutrals could be due to charge-exchange between trapped ions and Saturn's neutral hydrogen disk.

THE production of auroral X rays and energetic neutral particles is well known in the Earth's magnetosphere (X rays¹; charge exchange energetic neutral particles²⁻⁵) and can be expected at Jupiter and Saturn. In the case of the outer planets, besides

charge exchange with the planetary exospheric neutrals, the magnetospheric particles are also subject to similar loss processes due to interaction with the neutral clouds emitted from satellites⁶.

We present heré observations of the Voyager 1 spacecraft obtained a few days before encounter of the Saturn magnetosphere in November 1980. As Voyager 1 has no special experiment onboard for X-ray and neutral particle detection, we use the sensitivity and directional measurements of the LECP (low energy charged particle) analyser to identify the neutral radiation above the charged particle background.

Method of detection

The method has been outlined earlier and will be summarized only briefly here. The LECP telescope uses a silicon detector of 96.5 μ m thickness and 0.08 cm² area to accumulate counts in eight separate sectors near the ecliptic plane. Electrons 400 keV are magnetically deflected and cannot reach the detector. A stepwise integration of the X-ray sensitivity of the silicon detector for channel PL01 which has an electronic threshold of 26–31 keV, yields an average sensitivity $\bar{\epsilon}_1 \approx 2.38\%/\text{keV}$, and for channel PL02 $\bar{\epsilon}_2 \approx 0.8\%/\text{keV}$ (E=31-60 keV). The detection process for energetic neutral particles is the same as for charged particles: the neutrals become ionized when they hit the detector surface and deposit their energy through ionization energy loss in the detector.

The energy thresholds for neutral or charged particles are:

PL01: 40-53 keV ($\varepsilon \approx 0.4$) PL02: 53-85 keV ($\varepsilon \approx 1$) PL03: 85-139 keV ($\varepsilon \approx 1$)

Figure 1 shows the trajectory of Voyager 1 for days 307-330, 1980 and the viewing directions of the eight sectors of the instrument. It can be seen that X rays and energetic neutrals escaping from the magnetosphere should appear in sector 5. Encounter of the bowshock occurred at ~23:26 UT on day 316 (11 November 1980), thus the days before 316 can be used for our study. Criteria for the identification of neutral radiation during the pre-encounter phase (Fig. 1 and Kirsch et al. unpublished data) can be summarized as follows:

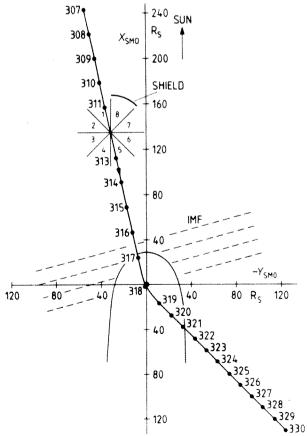

Fig. 1 Projection of the Voyager 1 trajectory on the ecliptic plane (days 307-330, 1980). Indicated are the eight viewing directions of the experiment. Sector 8 is permanently blocked by an aluminum shield.

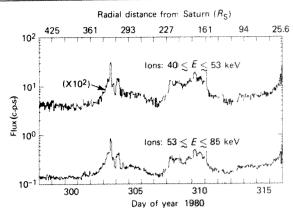

Fig. 2 Scan-averaged measurements of the ion channels PL01 and PL02 for days 298-316, 1980. Interplanetary particle acceleration by Corotating Interaction Regions (CIR) are evident beginning on days 302 and 308.

- (1) The interplanetary magnetic field must be nearly perpendicular to the Saturn-Sun line (in the nominal direction) to exclude charged particles escaping from the planet.
- (2) The pre-encounter measurements must not be disturbed by solar particles or particles accelerated in corotating structures (CIR) in the interplanetary medium.
- (3) Statistically significant enhancements above normal background must appear in the sector which is pointing towards the planet.
- (4) The energy spectrum measured within the sector pointing towards the planet should exhibit differences from spectra measured in the other sectors.
- (5) The additional flux (after subtracting background) must show a $1/R^2$ dependence (R distance from the planet).

The magnetometer data (ref. 10 and N. F. Ness, personal communication) show the interplanetary magnetic field direction to be almost perpendicular to the Saturn-Sun line, which satisfies criterion (1). To investigate the remaining criteria we show in Fig. 2 the scan-averaged particle measurements for days 298-314. Days 298-300 show the lowest count rates, which are probably due to penetrating galactic cosmic rays. Days 301-305 and 308-311 must be excluded due to the presence of ions associated with typical CIRs (see criterion (2)). On days 313-314 a slight increase was observed which is probably due to solar particles. Thus, we shall examine days 298-300, 306-307, 312-316 (~07:00 UT) in the context of criteria (3)-(5) for the presence of neutral radiation.

Observations

Figure 3a shows the sector count rates of channels PL01, 2, 3 for the selected days and the net flux (ΔP) for these channels after the galactic cosmic-ray background was subtracted. Figure 3b shows the count rate ratios before, and Fig. 3c after, subtraction of the galactic background flux (average of days 298, 299 and 300 has been used as galactic background). From day 312 onward sector 5 shows an increase in comparison with the neighbouring sectors which is ~4 times the statistical error. However, similar peaks exist in sector 1 throughout this period, and in sector 7 from day 313 onwards. Because both of these sectors are generally viewing the solar direction (Fig. 1), we attribute their response to low level fluxes of energetic solarinterplanetary particles. The solar background complicates our detection method. As pointed out in Fig. 1, sector 8 is an experiment calibration sector and cannot be used for further diagnostics of the solar particle contribution. Enhanced fluxes in sector 1 for channels PL02, 3 are most likely produced by the $\mathbf{E} \times \mathbf{B}$ drift. The enhanced rate in PL01, sector 1, is due to residual sensitivity to solar X rays, as the Sun was viewed by this sector at this time.

A clue to the identity of the observed fluxes can be obtained by examining the directional energy spectra through the channel ratios. It is evident from the channel ratios presented in Fig. 3b (background included) and especially Fig. 3c (background subtracted) that the additional flux counted in sector 5 has a

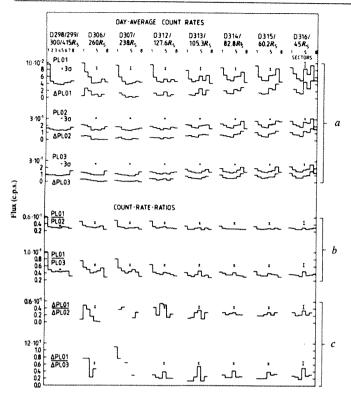

Fig. 3 a, Sector-averaged measurements for the days indicated for channels $PLO_{1,2,3}$. $\Delta PLO_{1,2,3}$ indicates that the galactic background is subtracted. The bars on sector 5 represent 3 times the statistical error. b, The count rate ratios PLO1/PLO2, PLO1/PLO3. c, $\Delta PLO1/\Delta PLO2$, $\Delta PLO1/\Delta PLO3$ (after background subtraction) show that sector 5 measured an additional flux which has a softer spectrum than the flux in neighbouring sectors.

softer spectrum than the flux of the neighboring sectors. As sectors 6, 7, 1, 2 and probably 3 are most likely to contain interplanetary particles, we compare sector 5 to only sector 4, in an attempt to estimate the additional flux in 5, as follows:

$$\Delta P_{1,2,3} = [(S_5 - S_4) - (Sq_5 - Sq_4)]_{1,2,3} \tag{1}$$

where $S_{5,4}$ are sector count rates and Sq_5 , Sq_4 the quiet time sector rates averaged over days 298, 299 and 300. The excess count rates obtained by use of equation (1) are then normalized by multiplication with $(R/45\ R_{\rm S})^2$ and listed in Table 1. The statistical errors have been calculated as

$$(\overline{\sigma}_{1,2,3})^2 = \{ (\overline{\delta S_4})^2 + (\overline{\delta S_5})^2 + (\overline{\delta Sq_4})^2 + (\overline{\delta Sq_5})^2 \}^{1/2}$$
 (2)

where

$$(\overline{\delta S_{4,5}})^2 = \frac{1}{5} \sum_{n=1}^{5} (\delta S_{4,5})_n^2 \left(\frac{R}{45R_S}\right)_n^2$$
 (3)

with n=1 to 5 representing days 312 to 316, 1980, and δSq_4 , δSq_5 are the statistical errors of the quiet days average 298, 299 and 300. The errors in the count rate ratios in Fig. 3b,c shown for each day were calculated using an equation similar to equation (2). Table 1 contains the normalized count rates $\Delta P_{1,2,3}$, the corresponding fluxes and the statistical errors calculated with equation (2). Note that the r.m.s. scatter in the rates for ΔP_1 is larger than the statistical error, and is likely to be due to time variations in this softest part of the spectrum.

The averaged excess count rates in sector 5 shown in Table 1 are statistically significant. The additional counts could be due to planetary or ring X rays, energetic neutrals and/or interplanetary charged particles reflected off the bow shock, so that only upper limits for the neutral radiation can be derived. The averaged X-ray flux j_X can be calculated from the count rate by

$$j_{X} = \frac{\Delta P_{1,2,3}}{A \varepsilon_{X} \Delta E_{X}} \tag{4}$$

where A is detector area, ε_X is X-ray efficiency and ΔE_X is the electronic channel width. Similarly, the neutral particle flux j_n

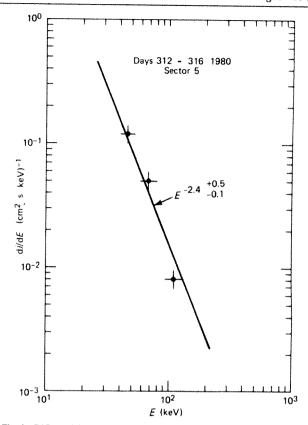

Fig. 4 Differential energy spectrum of the excess radiation, on the assumption that the detector response is due to energetic neutral hydrogen (Table 1).

can be calculated from equation (4), but using the appropriate values for ε and ΔE . The results, normalized to a distance of 45 $R_{\rm S}$ from the planet, are included in Table 1.

Discussion

The significance of the fluxes listed in Table 1 must be examined in the context of processes known or expected to take place in the vicinity of Saturn. Production of X rays can occur in auroral processes recently observed to take place at Saturn¹¹ over a relatively narrow range in latitude, $78^{\circ}-81.5^{\circ}$. If the electron precipitation takes place over the area of the observed UV signature $(A \sim 10^{19} \text{ cm}^2)$, that is, 2% of the surface), then the emitted photon flux at the source is given by

$$j_{\rm X} < \frac{j_{\rm X} 4\pi R^2 \Delta E}{A} = 3.4 \times 10^6 \text{ photons cm}^{-2} \text{ s}^{-1}$$
 (5)

with $\Delta E \sim 7$ keV, $R = 45 R_s$. The corresponding electron flux

† Averages normalized to 45 Rs.

precipitating into the atmosphere can be estimated by using a conversion efficiency of $\sim 2 \times 10^{-5}$ photons per electron¹²; we find $J \sim 1.7 \times 10^{11}$ electrons cm⁻² s⁻¹ which is some 10³ larger than the maximum fluxes measured by the LECP experiment within the magnetosphere of the planet¹³. Hence, we conclude that the observed upper limit, if interpreted in terms of X rays, cannot be reasonably related to precipitating magnetospheric electrons. The same conclusion is reached even if precipitation is assumed to occur over the entire visible hemisphere.

Another possible X-ray source is the interaction of radiation belt electrons with the rings of Saturn, which extend out to $\sim 2.5 R_s$. The surface area of the rings on the sunlit side is

$$S = (2.5 R_s)^2 \pi - (1 R_s)^2 \pi = 6 \times 10^{20} \text{ cm}^2$$
 (6)

If we assume -1% of the area to be filled with matter, the estimated X-ray production in the rings in the energy range 31-63 keV (PL02), is

$$J_{\rm X} = \frac{6.1 \times 4\pi (43 R_{\rm S})^2 \times 32}{6 \times 10^{18}} = 2.7 \times 10^7 \,\text{photons cm}^{-2} \,\text{s}^{-1}$$
 (7)

The corresponding electron precipitation is $\sim 1.4 \times 10^{12} \, \text{cm}^{-2}$ s^{-1} , again $\sim 10^4$ larger than the maximum flux measured by the same instrument in the magnetosphere with this channel¹³. Note that there is a sharp cutoff in particle fluxes at the edge of ring A, as shown by Pioneer 1114

The Voyager 1 UV experiment¹¹ found that Saturn is surrounded by a torus of neutral hydrogen with a concentration $n_{\rm H} \approx 10 {\rm cm}^{-3}$. The torus extends from $\sim 25 R_{\rm S}$ to $\sim 8 R_{\rm S}$ and its thickness could be $\sim 6 R_s$. Thus charge exchange processes between radiation belt protons and the neutral hydrogen concentration can be expected. For a flux estimation we use the cross-sections given by Tinsley⁵. The product σv (crosssection × velocity of the particles) is as follows for the lowest three channels

PL01:
$$(40-53 \text{ keV})$$
: $\sigma v_{H}^{+} \approx 3 \times 10^{-8} \text{ cm}^{3} \text{ s}^{-1}$

PL02:
$$(53-85 \text{ keV})$$
: $\sigma v_{H}^{+} \approx 1.4 \times 10^{-8} \text{ cm}^{3} \text{ s}^{-1}$

PL03:
$$(85-139 \text{ keV})$$
: $\sigma v_{H}^{+} \approx 3 \times 10^{-9} \text{ cm}^{3} \text{ s}^{-1}$

The lifetime against charge exchange is then

PL01:
$$\tau_1 = (n_H \sigma v)^{-1} = (10 \times 3 \times 10^{-8})^{-1} = 3.33 \times 10^6 \text{ s}$$

PL02:
$$\tau_2 = (n_H \sigma v)^{-1} = (10 \times 1.4 \times 10^{-8})^{-1} = 7.14 \times 10^6 \text{ s}$$

PL03:
$$\tau_3 = (n_H \sigma v)^{-1} = (10 \times 3 \times 10^{-9})^{-1} = 3.33 \times 10^7 \text{ s}$$

The LECP instrument measured an average density outside the orbit of Rhea at $E \ge 40 \text{ keV}$ of $\sim 5 \times 10^{-3} \text{ cm}^{-3}$ (ref. 13). Taking the neutral hydrogen cloud volume of $\sim 2 \times 10^{33}$ cm³ (ref. 11) we can estimate the total energetic ion content as

Received 13 May; accepted 7 July 1981.

- Blake, J. B. J. geophys. Res. 81, 6189 (1976). Tinsley, B. A. J. geophys. Res. 81, 6193 (1976).

- Cheng, A. F. Astrophys. J. 242, 812 (1980).
 Kirsch, E., Krimigis, S. M., Kohl, J. W. & Keath, E. P. Geophys. Res. Lett. 8, 169 (1981)

$$N = nV = 5 \times 10^{-3} \text{ cm}^{-3} \times 2 \times 10^{33} \text{ cm}^{3} = 10^{31}$$

The total energetic neutral particle production is given by

$$\dot{N} = \frac{nV}{\tau} = \frac{10^{31}}{10^7} = 10^{24} \text{ neutrals s}^{-1}$$

The loss rate may be obtained by estimating the total surface area of the neutral hydrogen disk,

$$A \simeq 2\pi [(25 R_S)^2 - (8 R_S)^2] \simeq 1.3 \times 10^{23} \text{ cm}^2$$

Thus energetic $(E \ge 40 \text{ keV})$ neutrals are lost at a rate

$$\frac{\dot{N}}{A} = \frac{10^{24}}{1.3 \times 10^{23}} \sim 8 \text{ cm}^{-2} \text{ s}^{-1}$$

The flux at 45 R_s would be decreased by a factor $\sim (20/45)^2 =$ 0.2, that is, N/A would be ~ 1.6 cm⁻² s

We now need to compare the expected flux at $45 R_s$ with the observations as summarized in Table 1. The differential flux from Table 1 has been plotted in Fig. 4; the form of the spectrum can be described by a power law of the form $E^{-\gamma}$ with $\gamma \sim 2.4$. To obtain the total flux we evaluate the integral

$$J = \int_{40 \,\mathrm{keV}}^{\infty} KE^{-2.4} \,\mathrm{d}E$$

and find $J \sim 4.3 \text{ cm}^{-2} \text{ s}^{-1}$. This value compares well with the expected value of $\sim 1.6 \text{ cm}^{-2} \text{ s}^{-1}$ derived above.

We have demonstrated the existence of radiation above the detector background emanating from the vicinity of Saturn, upstream from the bow shock. The excess counts are most plausibly attributed to neutral radiation, that is, X rays and/or neutral energetic particles. Estimates of the number of energetic electrons necessary to produce the observed counts by precipitation in either the saturnian auroral regions or the rings are too high by factors $\sim 10^3 - 10^4$ over electron intensities observed within the magnetosphere of Saturn. Thus the observed excess counts are probably not due to X rays even if satellite surfaces are considered as possible X ray sources. We conclude that charge exchange of energetic ions with satellite tori is an important loss mechanism at Saturn as well as at Jupiter15

The efforts of many at APL/JHU, the Universities of Maryland and Kansas and Bell Laboratories contributed to this investigation. We thank our colleagues on the LECP team: T. P. Armstrong, W. I. Axford, C. O. Bostrom, E. P. Keath and L. J. Lanzerotti for various contributions, J. F. Carbary for assistance with graphics, and especially L. J. Lanzerotti for useful comments. This research was supported in part by NASA under Contract N00024-78-C-5384 between The Johns Hopkins University and the Department of the Navy, and under subcontract to the University of Maryland.

Topology of Saturn's main magnetic field

M. H. Acuña, J. E. P. Connerney & N. F. Ness

NASA/Goddard Space Flight Center, Laboratory for Extraterrestrial Physics, Greenbelt, Maryland 20771, USA

The Voyager 1 magnetic field observations at Saturn confirm the principally dipolar topology of the planetary magnetic field and suggest the need for more general models which incorporate non-potential field sources external to the planet and within the planetary magnetosphere.

THE close flyby of Saturn at 3.07 R_s (1 $R_s = 60.330$ km) by Voyager 1 in November 1980 provided a second opportunity to study in situ the intrinsic planetary magnetic field. The first detection of the Saturnian field was accomplished by experiments aboard Pioneer 11 during its close flyby of Saturn at $1.35 R_s$ in September 1979^{1-4} . The most surprising characteristic derived from these magnetic field measurements was the near-alignment of the magnetic axis with the rotational axis of the planet. A small but non-zero axial displacement with respect to the planet's centre was also obtained. These features and the purely dipolar nature of the planetary field have significant implications for the general problem of the generation of magnetic fields by massive rotating objects.

The detection of Saturn at kilometric and hectometric wavelengths by the Voyager planetary radio astronomy experiment and identification of periodicities at 10:66 indicate that emissions originate from a restricted range of planetcentred longitudes⁵. This constitutes a paradox in terms of what would be intuitively expected from an axisymmetrical magnetic field, assuming that the emissions originate near the feet of the field lines. A more detailed analysis of the data obtained by Voyager 1 during its encounter with Saturn is presented here, with the emphasis on the uncertainties associated with the determination of model parameters describing the main magnetic field. The results of a preliminary analysis use data available immediately after the time of the encounter. Since then determinations of spacecraft attitude, position and alignment of the magnetometer sensors with respect to the main body of the spacecraft have been made, which can have a direct impact on the models derived from the observations. The independent results obtained from Voyager 1 allow a more general interpretation of Pioneer 11 observations and provide an insight into the phenomena taking place in the saturnian magnetosphere.

The flyby trajectories for Pioneer 11 and Voyager 1 were such that different ranges of planet-centred latitudes, longitudes and corresponding radial distances were sampled during each encounter. These characteristics are illustrated in Fig. 1 where the sub-spacecraft latitude and longitude for each trajectory during the closest approach phase are shown. The planetocentric radial distance to each spacecraft is indicated as well as the spacecraft event time (SCET) for Voyager 1. Figure 1 shows that the Pioneer 11 trajectory is largely equatorial, remaining within $\pm 6^{\circ}$ of the planetographic equator for $r < 8 R_s$.

In contrast, Voyager 1 approached Saturn from the south, reaching a maximum latitude of -41° at a radial distance of $3.14 R_s$ just before periapsis at $3.07 R_s$. Voyager 1 crossed Saturn's equatorial plane into the northern hemisphere at $6.3 R_s$ while outbound from periapsis. The larger latitude coverage of Voyager 1 is important to the modelling process, primarily because it allows a more accurate determination of hemispherical asymmetries, such as the polar offset derived from the Pioneer measurements^{2,4}. Note also in Fig. 1 the narrow range of planet centred longitudes sampled by Pioneer 11 inside $6 R_s$ ($\sim 120^{\circ}$). Voyager 1, in addition to the greater

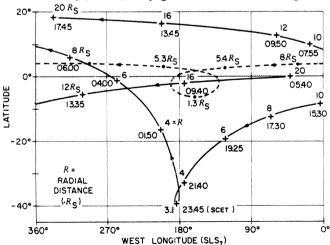

Fig. 1 The close flyby trajectories of Voyager 1 (solid line) and Pioneer 11 (dashed line) in Kronographic coordinates. The locus of sub-spacecraft points in SLS-longitude and latitude is shown. Voyager 1 crossed the equatorial plane from north to south at $20~R_{\rm S}$, reaching a maximum latitude of -40° . In contrast the Pioneer 11 trajectory remained within $\pm 6^{\circ}$ of the equator. SCET, spacecraft event time.

latitude coverage, extends this range to $\sim 135^{\circ}$, although it remains entirely in the southern hemisphere within the same radial distance range.

The analysis of magnetic field observations along a spacecraft flyby trajectory has been described elsewhere and presents several problems related to the uniqueness and uncertainties of parameters in the mathematical models derived from the measurements⁷⁻⁹. The usual assumption made is that the observations are performed in a region that is current-free, that is, external (or internal) to the sources of the measured magnetic field $(\nabla \times \vec{B} = \mu_0 \vec{J} = 0)$. In these conditions, the field can be represented as the gradient of a scalar potential function V, as $\vec{B} = -\nabla V$. The scalar potential has traditionally been represented by means of spherical harmonic functions with suitably normalized coefficients¹⁰. Two potential functions are normally used, one representing sources which reside in the interior of the planet and a second one which accounts for sources outside the region where the measurements are obtained. This approach was used in the preliminary report on the Voyager 1 magnetic field observations at Saturn⁶. The condition of $\nabla \times \vec{B} = \mu_0 \vec{J} = 0$ is reasonably well satisfied within the radial range $R < 6R_s$, 48-s averages of magnetic field data were used to derive a leastsquares model fit to the observations using an interior, centred, tilted dipole and an exterior uniform field (I1E1 spherical harmonic model with internal and external components both first order). These results yielded the Schmidt normalized coefficients reported by Ness et al.⁶, that is: $g_1^0 = 0.209 \,\text{G}$, $g_1^1 = 0.00220 \text{ G}, h_1^1 = 0.00124 \text{ G}; \text{ external } G_1^0 = -8.8 \times 10^{-5} \text{ G},$ $G_1^1 = -4.2 \times 10^{-5}$ G and $H_1^1 = 3.3 \times 10^{-5}$ G. These results agree well with those reported by the Pioneer 11 investigators 1-4. With respect to the dipole displacement from the centre of the planet, the preliminary Voyager 1 studies placed an upper limit of $0.02 R_{\rm S}$ to any possible offset. The most significant new results were that the 0.04 R_s northward offset derived from the Pioneer 11 measurements is not reproduced in the Voyager 1 models, and that a definite dipole tilt of $\sim 0.7^{\circ}$ at a SLS¹¹ longitude of 331° was obtained. Note, however, the assumptions made in the model: current-free observations as well as a uniform external field.

Additional studies of the magnetic field data obtained during the traverse of the middle magnetosphere of Saturn (6 $R_s \le R \le 16 R_s$) have led Connerney et al.¹² to conclude that Saturn is surrounded by an eastward-flowing ring current which extends from 8.5 to $15.5 R_S$ in the equatorial plane and with a total thickness of $\sim 5R_s$. The current density in this sheet decreases proportionally to distance from the planet and is an order of magnitude smaller than that found at Jupiter. A more realistic magnetic field model for the analysis of Saturn's main field in which the distributed ring currents are explicitly modelled is constructed as follows: an I1E1 model is first least-squares fitted to the observations obtained within $\sim 6 R_S$ of close approach. These internal field parameters constitute a first approximation to Saturn's main field: the external terms (uniform field) approximate the field due to magnetospheric currents. The internal field is then subtracted from observations obtained within $\sim 30 R_s$ and the resulting external field is modelled in terms of an azimuthal ring current. The (solenoidal) field of the ring currents is then adopted as a more accurate external field representation, and assumed in a least-squares fit to determine new internal field coefficients (I1E0).

This procedure does not necessarily converge to a unique set of model parameters and each iteration step must be guided by appropriate physical constraints as well as results from correlative investigations. The results of such a study are given in Table 1. As done previously, 48 s-averaged field values obtained for $R < 8R_s$ have been used. Two weighting schemes have been used, one in which uniform weights are attached to the measurements $(\omega_i = 1)$ and a second one in which the weights have been chosen inversely proportional to the magnitude of the measured field $(\omega_i \propto [0.01 \times |\vec{B}_i|]^{-1})$. The first is appropriate for observations assuming a uniform (random) noise level and the second for observations assuming a noise component which is

^{*} Ref. 6.

proportional to the local field magnitude. The derived tilt angles and longitude of the tilt are also indicated in Table 1. The r.m.s. of the residuals of the model fits show that all these models fit the observations very well. As discussed by Ness et al.⁶, second-order (quadrupole) models do not provide a significant reduction in the residuals. The implication of this is that the derived offset of the dipole from the centre of the planet is small and consistent with zero to the level that can be ascertained from the magnetic field measurements alone. Note from Table 1 that models incorporating the field due to the ring current explicitly, rather than the I1E1 models which represent this field as uniform, do not provide a significant reduction in the r.m.s. of the residuals. This is due to the model residuals being dominated by a localized and presumably non-potential feature unrelated to the ring current or internal field.

We now illustrate the residuals in the three orthogonal field components, ΔB_R , ΔB_{\bullet} , ΔB_{\bullet} after the internal field model plus that due to the modelled ring current are subtracted from the observations. This is shown in Fig. 2 for case 5 in Table 1. This particular model was chosen primarily for convenience. In general, the magnitude of the residuals is small, <10 nT. Some still unresolved engineering and attitude determination problems are evident in Fig. 2. The 'disturbance' at 00:43 UT and extending until ~01:00 is associated with a spacecraft roll manoeuvre and the lack of sufficiently accurate knowledge of spacecraft and therefore magnetometer sensor orientation during the manoeuvre. The sensor alignment with respect to the spacecraft reference axis was determined by means of an onboard calibration coil¹³ and the analysis of spacecraft manocuvres in steady-state fields during both cruise and planetary encounters at Jupiter and Saturn. This orientation is known to better than ±0.2°. Also evident in Fig. 2 are small discontinuities associated with instrument range changes, the updating and interpolation of spacecraft attitude matrices and analogue-todigital converter digitization uncertainties. In addition, the spacecraft limit cycle (±0.06°), which is unmodelled, contributes to the observed noise where the ambient field is large (1 nT in 103 nT).

The largest contribution to the residuals occurs between 21:00 on day 317 and 05:00 on day 318, particularly in the radial component, ΔB_R . An additional feature can be seen superimposed on ΔB_R and ΔB_{θ} curves occurring between 22:30 on day 317 and 01:00 on day 318. This quasi-abrupt enhancement of the residuals seems to be associated with a magnetospheric current system quite distinct from the azimuthal current system already modelled. This feature was observed as Voyager 1 passed through the dusk sector of Saturn's magnetosphere, nearly coincident with closest approach. In planetocentric coordinates, the spacecraft was moving primarily in latitude at this time (Fig. 1), actually reversing momentarily its westward motion, as viewed from Saturn.

The residuals of internal magnetic field models are dominated by a highly correlated, very localized and presumably nonpotential field contribution near periapsis. Thus the current representations of the field are not sufficient to describe the observed field to better than 10 nT. This includes models explicitly incorporating distributed azimuthal currents as well as potential field models. Note that the residuals illustrated in Fig. 2 are evidence of local currents but the plotted field components are not the magnetic field signature of such currents. The plotted residuals are only that part of the observed field that cannot be expressed with the limited models available. Certainly some part of the field contributed by local currents has been absorbed by the internal field coefficients and therefore does not appear in the residual plot. The problem of separating the different contributions to the observed field due to the planetary field, the ring current, and the other local currents is the primary challenge to be met in obtaining better estimates of Saturn's internal field. To do so requires a model of the inner magnetosphere in which the very localized currents are explicitly taken into account.

Several model current systems that might be expected on physical grounds to be active in this region of Saturn's magnetosphere are being considered. For example: (1) fieldaligned currents associated with the interaction of Saturn's corotating magnetosphere with a satellite, or particle ring, reminiscent of the currents linking Jupiter and its satellite Io, as observed by Voyager 114. The most promising candidates here seem to be the E-ring and the satellite Dione. Voyager passed \sim 20,000 km north of the field line linking Dione at \sim 00:10, day 318, as it traversed the dusk sector. (2) A dawn-dusk system of Birkeland currents driven by the solar wind-induced asymmetry. (3) A system of Birkeland currents driven by a nonazimuthally symmetric torus or an as yet unidentified surface magnetic anomaly similar to that proposed for Jupiter12 enhancement of high energy (1-2 keV) electron fluxes observed by the Voyager 1 plasma experiment in the dusk sector,

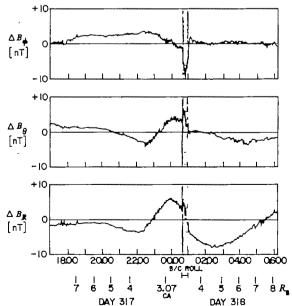

Fig. 2 Plot of the component residuals, ΔB_{π} , ΔB_{ϕ} and ΔB_{ϕ} obtained after subtracting a dipole model plus the field from the ring current as determined from the Voyager 1 observations. The abrupt enhancement observed between 22.30 and 01.00 h of day 318 is interpreted as evidence for a localized current system flowing in the inner saturnian magnetosphere.

[†] Ring current model of Connerney et al. 12

concomitant with the magnetic field signature, has been described by Sittler et al16. As additional correlative observations become available, we hope to offer a more detailed model.

Of the models in Table 1, cases 2 and 3, derived using weights inversely proportional to the local field magnitude, minimize the effect of the localized current system encountered near periapsis. This unmodelled 10-nT perturbation is less likely to affect significantly the internal field coefficients in the weighted leastsquares fits compared with the unweighted cases, as larger errors are tolerated in higher fields. Case 3 in Table 1 is regarded as best representing the global characteristics of the saturnian field, as deduced from Voyager 1 observations alone.

To estimate model parameter uncertainties we need to assess the impact on the internal field coefficients of the unmodelled current system. Lacking a detailed model, we can estimate the parameter uncertainties by comparing models relatively unaffected by the currents (weighted fits) with those that are more strongly dependent on the residuals near closest approach (unweighted fits). Such a comparison suggests a dipole moment of 0.21 ± 0.005 G $-R_s^3$, tilted $1.0 \pm 0.3^\circ$ towards an SLS longitude of $340^{\circ} \pm 20^{\circ}$. The northward displacement of the dipole by 0.04 R_s deduced from the Pioneer 11 observations is not

substantiated by the Voyager 1 observations, although we must take into account that the near-equatorial trajectory of Pioneer 11 was poorly suited for detecting hemispherical asymmetries. Voyager 2 will fly by Saturn in August 1981; its close encounter trajectory will provide a latitude coverage of $\sim \pm 30^{\circ}$ within 8 R_s and facilitate a more accurate estimate of a possible dipole polar

Certain aspects of Saturn's main magnetic field relevant to the planet's interior have been discussed by Stevenson¹⁷. In particular, the unexpectedly small dipole moment seems to be consistent with the gravitational settling of helium, which leads to a much smaller electrically conducting and convecting region than would be expected of a homogeneous distribution of hydrogen and helium. The IR studies by Voyager 1 have demonstrated such an atmospheric depletion of helium, obtaining an 11% helium mass fraction at Saturn as compared with the 19% observed at Jupiter and expected on a cosmochemical basis¹⁸. The near alignment of Saturn's magnetic and rotational axes is likewise consistent with the differential rotation of the conducting core in Stevenson's model of Saturn's interior¹

We thank our colleagues on the Voyager team, especially J. Scudder and E. Sittler of the plasma experiment for helpful discussions. We also thank R. Thompson and F. Ottens for the analysis of these data.

Saturn's ring current and inner magnetosphere

J. E. P. Connerney, M. H. Acuña & N. F. Ness

NASA/Goddard Space Flight Center, Laboratory for Extraterrestrial Physics, Greenbelt, Maryland 20771, USA

The Voyager 1 magnetic field observations at Saturn reveal an equatorial system of (eastward) azimuthal currents, very similar in certain respects to that responsible for the jovian magnetodisk.

IN November 1980, Voyager 1 became the second spacecraft to obtain in situ observations of the magnetosphere of Saturn: little more than a year earlier, the Pioneer 11 spacecraft returned the first evidence of Saturn's magnetosphere. Analyses of the Pioneer 11 magnetic field observations^{1,2} revealed a dipolar planetary magnetic field of moment $0.21 \,\mathrm{G} - R_{\mathrm{S}}^{3}$, rather less than that expected on the basis of scaling laws^{3,4}. [The units $G-R_s^3$ are dimensionally equivalent to standard units of magnetic dipole moment, the numerical value having been divided by the cube of the planetary radius.] More surprising was the near alignment of Saturn's rotational and magnetic dipole axes, a unique characteristic among the known planetary dynamos and therefore of central interest in dynamo theory5. A preliminary estimate of 0.7° angular separation of Saturn's rotational and magnetic dipole axes has recently been derived from the Voyager 1 magnetic field observations⁶

Saturn's lack of an appreciable dipole tilt results in an observational limitation insofar as studies of magnetospheric phenomena in situ by spacecraft are involved. Figure 1 shows the trajectories of each spacecraft to encounter Saturn (Pioneer 11 (P11) in September 1979; Voyager 1 (V1) in November 1980; and Voyager 2 (V2) in August 1981) in a cylindrical (ρ, z) planet centred coordinate system, which in this case is practically identical to the magnetic equatorial coordinate system. Each spacecraft remains essentially at constant magnetic latitude for a large percentage of the encounter, with only one (V2) or two

(V1, P11) crossings of the magnetic equator. Particularly evident is the rather singular nature of Pioneer 11's trajectory, which traced a nearly identical path outbound from periapsis as inbound. In contrast to the periodic variations in the magnetic

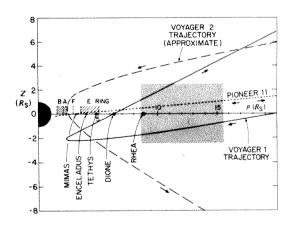

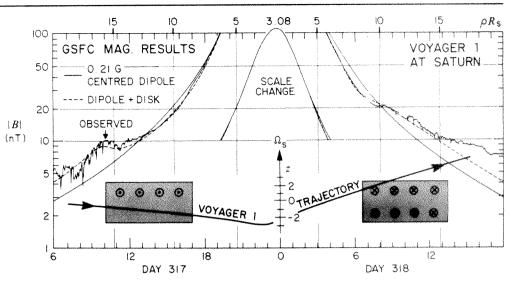

Fig. 1 Trajectories of Pioneer 11, Voyager 1 and Voyager 2 at Saturn in a cylindrical planetocentric equatorial coordinate system. Positions of the major satellites and rings are indicated; satellite diameters are exaggerated by a factor of 10. Stippled region is the region of (model) distributed currents in Saturn's magnetosphere.

Fig. 2 Magnitude of observed magnetic field within $\sim 20~R_{\rm S}$ of Saturn and comparison with an internal dipole model (solid line) and a model containing a dipole and distributed ring currents (dashed line) discussed in test. The Voyager 1 trajectory is illustrated beneath these observations, showing distance from the equator as a function of time. Note the different scale used for vertical dimension of trajectory insert.

field and charged particle environment observed in Jupiter's magnetosphere concomitant with the regular variation of magnetic latitude due to that planet's rotation and dipole tilt (9.6°) , at Saturn, the observations reflect more the systematic co-variation of ρ and z.

The Voyager 1 magnetic field observations at Saturn are shown in Fig. 2, in which the magnitude of the observed magnetic field is compared with that of a 0.21 G - R_s^3 centred dipole. The departure from a dipole is noticeable during the approach to periapsis at radial distances exceeding $\sim 8 R_{\rm s}$. whereas outbound the differences are noticeable at radial distances in excess of $\sim 5R_S$. The observed field magnitude is appreciably less than that of the model dipole at small radial distances ($\rho < \sim 10R_s$) and greater than the model dipole in the more distant magnetosphere. These characteristics can be understood by introducing a model current system similar to that originally applied to observations of the jovian magnetodisk⁷. In this model, large-scale azimuthal currents flow eastward in an annular disk extending from $8.5 R_s$ to $15.5 R_s$ in Saturn's equatorial plane. The current is distributed uniformly in \hat{z} over the total disk thickness of $5R_s$ and decreases with radial distance from Saturn as $1/\rho$. The physical dimensions of this annulus roughly correspond to those of the 'extended plasma sheet' observed by the Voyager 1 plasma experiment⁸. Because the radial extent of the disk, $7 R_s$, is almost equal to the thickness, and considering the radial decrease in model current density, we refer to this phenomenon as a ring current rather than a magnetodisk to distinguish it from the more two-dimensional geometry of the jovian azimuthal currents. The model illustrated in Fig. 2 has a current density of $\sim 0.3 \times 10^6 \text{ A}/R_S^2$ $(\sim 0.1 \text{ mA km}^{-2})$ at the inner edge of the annulus, decreasing to $\sim 0.15 \times 10^6 \text{ A/R}_s^2$ at its outer edge. These current densities are about an order of magnitude less than those observed at Jupiter.

The derived model is a result of a vector fit to the Voyager observations and self-consistently satisfies both of the observed radial and vertical field components. The magnetic field of this equatorial system of currents is largely solenoidal. The near axis field is essentially vertical and oppositely directed to Saturn's (equatorial) main field; at larger distances the two add. Above the plane of symmetry of the distributed current system, the radial field is positive outward and below the equator, positive inward, increasing approximately linearly with distance, Z, from the equatorial plane for Z < D. Thus the field lines are radially stretched in a manner reminiscent of the stretching or drawing out of field lines in the near equatorial regions of the jovian magnetodisk.

The total azimuthal current, and the distribution of the current in $\hat{\rho}$, is inferred from the radial dependence of the external vertical field component. The external field is estimated by subtracting from the observations a best-fitting dipolar

 $(0.21~{\rm G-R_s^3})$ internal field. The distribution of that current in \hat{z} is inferred from the variation of the radial component of the external field. While the Voyager trajectory at Saturn did not permit numerous traversals of the current-carrying region as at Jupiter, it did provide observations within the distributed currents sufficient to allow the localization of source currents in Saturn's magnetosphere. An earlier model⁶, characterized by currents confined to an annular disk of radial extent 8-16 R_s , with a total thickness of $4R_s$, fits the observations about as well if the current density is increased such that the linear current density in Saturn's equatorial plane remains unchanged.

The near-axis field of the azimuthal currents is ~ 10 nT, which agrees well with the external field inferred from spherical harmonic analysis 6.9 of the Voyager 1 encounter observations. The field of this model current system reaches a maximum (12.5 nT) along the trajectory as Voyager 1 approaches the inner edge of the annulus at hour 6, day 318 while outbound from periapsis. The field enhancement observed as Voyager 1 approached the outer edge of the annulus at 15.5 $R_{\rm s}$ while inbound to periapsis is understood as an edge effect. The lack of such a localized enhancement of the modelled field during the outbound traversal is a simple consequence of Voyager 1's higher latitude at this time. Beyond 15 $R_{\rm s}$ outbound the discrepancy between the model field and the observations grows as the contribution of unmodelled cross-tail currents 10 to the total field grows.

A model of Saturn's magnetosphere, constructed by superposition of the dipolar $0.21 G - R_s^3$ internal field and that of the model ring currents, is compared in Fig. 3 with a dipolar magnetic field. The radial stretching of field lines in the equatorial plane and the non-dipolar nature of the model field is evident at radial distances exceeding $5 R_s$. The global character of the field due to the azimuthal currents ensures a departure from a dipolar magnetic field configuration at high latitudes as well. This axisymmetric model magnetosphere neglects the

Table 1 Times at which Voyager 1 encountered field lines which pass through the equator at a radial distance occupied by a known absorber

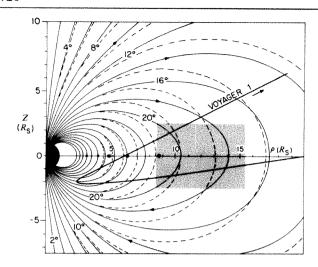

Fig. 3 Meridian plane projection of magnetosphere field lines for a dipolar field model (dashed) and a model containing a dipole and distributed ring currents (solid) discussed in the text. Field lines are drawn for 2° increments in co-latitude. Positions of the major satellites Mimas, Enceladus, Tethys, Dione, and Rhea are as in Fig. 1.

contribution of magnetopause and tail current systems driven by the solar wind interaction which become non-negligible in the more distant magnetosphere ($R > 15 R_s$).

Saturn's ring current has important implications for chargedparticle motion in Saturn's magnetosphere, particularly the absorption of trapped radiation by its many satellites and rings. Satellite absorption is conceptually simple: all charged particles that, in the course of their mirroring or latitudinal bounce motion, intersect an absorber are removed from the local particle population. In practice, charged particle absorption signatures associated with satellite sweeping are energy and species dependent, reflecting particle drift motion and finite gyroradius effects as well as particle diffusion. Thus, a complete description of charged particle motion relevant to satellite absorption requires a knowledge of the magnetic field line geometry and field gradient and curvature drifts over the particle's bounce path.

The absorption signature observed by the Voyager 1 cosmic ray experiment¹¹ near the orbital position of Rhea illustrates well the effects of Saturn's ring current on charged particle trajectories. Indeed, the premature occurrence of the absorption signature observed by Voyager 1 outbound in the vicinity of Rhea was cited as evidence of non-dipolar deformations of Saturn's post-midnight magnetosphere¹¹. Given the model magnetosphere deduced from the magnetic field observations, we have traced field lines from the Voyager trajectory to the equatorial plane to arrive at the results presented in Table 1. times at which Voyager 1 encountered field lines which pass through the equator at a radial distance occupied by a known absorber. Also listed are the corresponding times assuming a dipolar model magnetosphere. The actual time at which the Rhea absorption signature was observed was $\sim 06:25$, day 318, which agrees very well with the model results presented here and ·10 min before that expected in a dipolar field.

The Rhea absorption signature was observed while Voyager 1 passed ~4° east of Rhea's orbital position. Magnetospheric plasma corotates from Rhea to Voyager 1 in ~7 min; in the

corotating reference frame protons drift eastward, in the corotational direction, and electrons drift westward. Observation of an absorption signature in the 0.6-MeV electron data11 was interpreted as evidence that the detector was responding to lower energy electrons, as electrons of energy >0.57 MeV (60° pitch angles) have drifted sufficiently in a dipole field that they trail Rhea in its orbit about Saturn. While we have not performed the required bounce-averaged gradient and curvature drift computation using our model field, we note that in the vicinity of Rhea's orbit Saturn's magnetosphere is sufficiently non-dipolar so as to cast doubt on longitudinal drifts computed with a dipolar field. The equatorial field gradient at Rhea's orbital distance is only ~0.6 that of a dipole field, and the local field magnitude is also ~ 0.66 that of a $0.21 \,\mathrm{G} - R_5^3$ dipole. Particles of a particular energy with 90° pitch angles will thus drift with ~50% greater velocity than identical particles in a dipole field. In addition, the variation of the longitudinal drift rate with pitch angle is greater in the ring current model field than in a purely dipole field. Finally, we note that pitch angles derived assuming a dipole field geometry can be substantially in error (~20°) in the region of the magnetosphere where the Rhea absorption feature was observed. We conclude that in the cosmic ray experiments the 0.6 MeV detector may well have been responding to electrons with energies >0.6 MeV, as designed, and not to electrons below the nominal detection threshold of that instrument.

The total integrated ring current in Saturn's magnetosphere is $\sim 3 \times 10^6$ A, only a few per cent of the integrated azimuthal current flowing in the jovian magnetodisk. The near axis field of Saturn's ring current is ~ 10 nT; the ratio of this quantity, $B_c(0)$. to Saturn's equatorial dipole field, B_e , is $\approx 4.8 \times 10^{-4}$. The same quantity computed from a model of Jupiter's azimuthal disk currents⁷ using $B_r(0) \sim 200 \text{ nT}$ and $B_e = 4.2 \text{ G}$, is also $\sim 4.8 \times$ 10⁻⁴. This implies^{12,13} that the total kinetic energy of trapped particles in the magnetosphere (E) scales with the available dipole magnetic energy outside the planet's surface (U). We note that while the ratio E/U is the same for both of the giant planets, Saturn's total E is little more than 0.15% of Jupiter's. The same ratio, applied to the Earth's magnetosphere (assuming $B_e \sim 0.3$ G), leads to a near-axis ring current field of ~ 14.5 nT. This is well within the 10-23 nT range estimated for the nearaxis field of the Earth's quiet ring current on the basis of models fitted to Imp magnetic field observations¹⁴. That three so vastly different magnetospheres apparently have almost the same E/Uratio is indeed surprising and suggests a limiting process whereby such a ratio is maintained.

Saturn's magnetosphere is well approximated by an axisymmetric, but non-dipolar field within $\sim 15 R_s$ of the planet. The non-dipolar nature of Saturn's magnetosphere is evident at radial distances exceeding $\sim 5 R_s$ and can be expected to have a significant role in charged-particle motion in Saturn's magnetosphere. Beyond 15 R_s , the asymmetries introduced by the solar wind interaction become non-negligible, particularly the formation of a magnetotail in the night-side magnetosphere. We suspect that Saturn's ring current is a permanent feature of Saturn's magnetosphere, much like the jovian magnetodisk. A better understanding of possible temporal characteristics of Saturn's magnetosphere must await analysis of Pioneer 11 observations already obtained and those to be obtained by Voyager 2 in August 1981.

We thank our Voyager colleagues and colleagues at Goddard Space Flight Center, particularly T. J. Birmingham and D. P. Stern, for useful discussions.

Arc structure in Saturn's radio dynamic spectra

A. Boischot', Y. Leblanc', A. Lecacheux', B. M. Pedersen' & M. L. Kaiser'

*Observatoire de Paris, F-92190 Meudon, France †Goddard Space Flight Center, Code 695, Greenbelt, Maryland 20771, USA

The dynamic spectra of Saturn's kilometric radiation show arc structures whose main characteristics are described and compared with those observed in the decametre emission of Jupiter. The origin of the arcs is probably similar for the two planets.

ONE of the most spectacular findings of the Voyager 1 planetary radio astronomy experiment (PRA) was the discovery of nested arc-like structures in the dynamic spectra of Jupiter's decametric emission. These arcs have curvature in either a direction towards increasing time (vertex early arcs or VEA) or decreasing time (vertex late arcs or VLA)^{1,2}. Several explanations for their structure have been proposed³⁻⁷. Similar arc structures are also evident in Saturn kilometric radiation (SKR) (see Fig. 1). These structures appear superimposed on the strong intensity modulation which is controlled by the rotation of the planet (sub-Voyager longitude in SLS) and on fast and narrow band fluctuations which give a very large variability to the PRA observations on a 6-s, 20-kHz scale. This very fine structure seems to be always present.

Characteristics of the arcs

The arc structure for Saturn, although easy to recognize, is not as regular as it is for Jupiter. This is due to the superposition of fine structure, and also because the amplitude of modulation of the emission by the arcs is small, only a few decibels on average, compared with 10 or 20 db for Jupiter. Thus for each rotation only a few arcs are clearly distinguished. The arc structure extends over the whole frequency range of the emission, but is often more clearly seen near the high frequency limit. Some phenomenon (possibly absorption or refraction) probably fixes the low frequency limit of the observed emission, and this prevents the lower legs of the arcs being seen to their full extent.

During the month around encounter the shapes of the arcs do not change much with time or SLS (Fig. 2). We can draw an 'average arc' with its vertex around 400 kHz and symmetrical curvature (on a linear frequency scale) around this vertex. The total extent is about 20 min and the shape is the same for VEA and VLA. In several cases, successive arcs are separated by 10-30 min, so that they appear to be nested like jovian arcs, but this nesting is not as regular as for Jupiter.

The arc structure could be seen on PRA records even when the spacecraft was far away from Saturn: arcs were very clearly observed as early as July 1981, when Voyager 1 was still at 1 AU. From that distance, the arcs appear more pronounced than when observed closer to the planet (probably because the amplitude of modulation is larger) and their shape is slightly different, the vertex being at lower frequencies (Fig. 2c).

The few arcs which are clearly recognized during each rotation are generally at quite different SLS positions. We can study their occurrence in SLS by adding up several rotations. Figure 3 presents two histograms of the position of the arcs for the preand post-encounter periods. For each period, a particular sense of arc dominates: VEA before encounter and VLA after encounter, irrespective of longitude.

Arcs of opposite curvature are also observed superposed on the dominant variety, but only in the range of longitudes where the total emission is most intense. Hence, the sub-spacecraft longitudes of these arcs change after encounter. Saturn emission is, at least partly, circularly polarized, but the arc structure does not seem to affect this polarization. We conclude that the sense of polarization remains constant before and after encounter and that the two families of arcs that we recognize during one rotation have the same sense of polarization. A more detailed analysis is required to see whether the arc structure corresponds to a modulation of the degree of polarization.

The difference in the dominant sense of curvature of the arcs between pre- and post-encounter periods can be interpreted in two ways:

- (1) The difference could be due to a latitudinal effect because the average latitudes of the spacecraft were different during the inbound (~8°) and outbound (~26°) paths; but whatever the origin of the arc mechanism, it would be more natural to expect a change in the shape of the arcs rather than in their sense of curvature.
- (2) The change in the sense of the arcs is a local time effect, a source at fixed position in local time (as invoked to explain the pre- and post-encounter change of the occurrence probability histograms of the emission with sub-Voyager SLS) being seen from two nearly opposite directions before and after encounter. As a local time explanation is more natural for the occurrence histograms, it is also more likely for the change of arc direction.

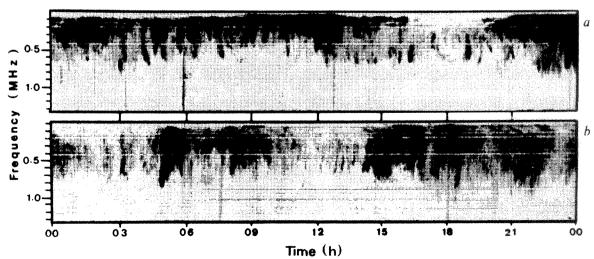

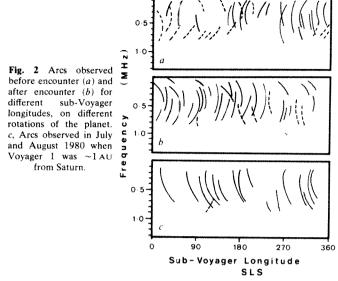

Fig. 1 Dynamic spectra of Saturnian kilometric radiation (SKR) for a day before encounter (10 November 1980, a) and a day after encounter (20 November 1980, b). In each plot the darkness is proportional to signal intensity as a function of wave frequency and hour of the day. More than two rotations of the planet are covered.

The arc structure and the reversal of the direction of the dominant family are clear.

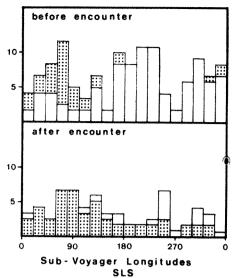

Fig. 3 Histogram of the arc-direction as a function of sub-Voyager longitude in SLS. White corresponds to vertex early arcs (VEA) and dark to vertex late arcs (VLA). At every dominate before counter and VLA after encounter, while arcs of the opposite direction are more localized in longitude. Because longer period studied before encounter more arcs were seen during this period.

Comparison with Jupiter

The arc structure in Jupiter appears mainly at frequencies larger than 1 MHz. At lower frequencies, the arcs are more difficult to follow, although many drifting features can be seen at the end of the low-frequency leg of the arcs, with their vertex between 5 and 10 MHz. On the other hand, Saturn's emission is observed only at frequencies lower than 1.2 MHz. This large difference in the frequency range of the emission must be considered when we compare the arc structure of the two planets.

The most important result is that arcs cover the whole frequency range of the emission from both Jupiter and Saturn. As the high frequency limit of Saturn's emission is fairly constant the arc shape is stable. In contrast the jovian arc shapes vary considerably with LCM. In particular the higher the frequency limit, the higher the frequency of the vertex. The inclination of the magnetic axis to the rotation axis is much more important for Jupiter than Saturn and explains the difference. As the jovian arc pattern varies consistently with the LCM, we consider that the variation of shape with LCM is principally due to the wobbling of the observer's position in magnetic coordinates due to this inclination. Such a variation does not exist on Saturn because the magnetic and rotation axis nearly coincide^{9,1}

Another comparison concerns the sense of the arcs and its change at encounter. If we compare the arcs of Saturn with the lesser arcs of Jupiter¹⁻², whose emission is not controlled by Io, the variations are similar. The lesser arcs are predominantly VLA before encounter and VEA after encounter, but both types of arc are always present. Hence, although the character of the dominant family is opposite, the reversal at encounter is observed for both planets. Thus the main characteristics of the arcs in Jupiter's and Saturn's emission are similar, even if their frequency ranges are different.

At Jupiter, several types of arcs have been identified²: at least two types of lesser arcs, and several types of Io-controlled and non-lo-controlled high frequency arcs, while only two are observed for Saturn. This probably requires several distinct sources of jovian emission while only one or two are necessary to explain the Saturn's arcs. The larger variability of the arc with longitude observed for Jupiter can be explained simply by the change in the magnetic latitude of the observer during one rotation due to the inclination of the magnetic axis to the rotation axis. Therefore the cause of the arcs is probably related to the magnetic field and the similarities between Saturn's and Jupiter's arc structures mean that they are probably due to the same physical mechanism.

Arcs in Saturn's radio spectra

J. R. Thieman* & M. L. Goldstein

*Advanced Systems Planning Division, ORI Inc, 1400 Spring St Silver Spring, Maryland 20910, USA †Code 692, Laboratory for Extraterrestrial Physics, NASA/Goddard Space Flight Center, Greenbelt, Maryland 20771, USA

Arcs appearing in the dynamic spectra of Saturn radio emission have been modelled using the same techniques as applied to jovian arcs. Their properties suggest a source region several tenths of a Saturn radius above the cloud tops in the late morning local time sector.

ARC-LIKE structures appear sporadically in the dynamic spectra of Saturn radio emission measured by the Voyager 1 planetary radio astronomy (PRA) experiment. Arcs were pervasive in the dynamic spectra of Jupiter emission 1-3 but they are not nearly as prevalent in Saturn data. There are some differences in the properties of the arcs from the two planets, but a model used to fit jovian arcs has also been successfully applied to Saturn arcs. The curvature and frequency range of the Saturn arcs are best fitted by assuming the source is along magnetic field lines with small L values $(L \le 5)$.

Figure 1 shows examples of Saturn dynamic spectra and the types of arcs which occur: both vertex-early and vertex-late arcs (appearing as opening and closing parentheses, respectively) are indicated. A search of dynamic spectra between June and December 1980 resulted in a set of 82 arcs but data gaps during this period preclude determination of an exact occurrence rate. Table 1 summarizes the similarities and differences between the catalogued arcs and the arcs seen in jovian dynamic spectra. As Boischot et al.4 have considered some of these characteristics. only some of the entries will now be discussed.

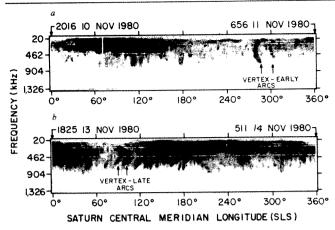

Fig. 1 Examples of arcs in the dynamic spectral plots of Saturn emission detected by the Voyager 1 spacecraft. Data from one rotation of Saturn before (a) and after (b) closest approach. The beginning and ending spacecraft data acquisition times are marked. Darkness is proportional to the signal strength computed for 1° longitude averages in each of the 70 frequency channels from 1.2 kHz to 1.32 MHz. The abscissa is the longitude of the meridian plane containing the spacecraft. Two vertex-early and two vertex-late arcs are indicated.

Although the right-hand polarization sense (as conventionally used by radio astronomers) is dominant for Saturn arcs, left-hand polarized arcs occur occasionally, mostly during closest approach to Saturn when the spacecraft trajectory was southernmost in latitude⁵. For the 82 arcs analysed, the duration ranged from 10 min to >1 h, with an average of \sim 45 min.

Figure 2 displays histograms of the minimum, maximum and vertex frequencies for the catalogued Saturn arcs. The average vertex frequency is slightly lower than the value of 400 kHz cited by Boischot et al.⁴, but their value was based on arcs identified near encounter only. The low frequency extent of the arc peaks sharply around 100 kHz, probably as a consequence of the plasma frequency cutoff due to the plasma density between the source and the spacecraft.

The most interesting difference between Jupiter and Saturn is that for the inbound passage of Voyager 1 to Saturn nearly all of the observed arcs had vertex-early curvature sense while the reverse was true outbound. The sense of curvature of some jovian arcs also shows some pre- and post-encounter dependence, but the dominant influence is longitude. Both vertex-early and vertex-late curvature are often superimposed, and the amount of curvature, the vertex frequency and the frequency extent for each type of curvature are directly dependent on jovian longitude. The inbound and outbound difference in curvature sense at Saturn is interpreted as a local time effect as there is some evidence that the source of emission is confined in local time.

Although differing means of arc generation are possible, the many similarities in the planets' arcs suggest similar mechanisms. Beaming of radio emission into a hollow conical sheet was a common hypothesis long before arcs were discovered. Previous modelling work demonstrated that a hollow conical beam which is centred on and rotating with a jovian magnetic field line can reproduce the observed jovian arcs if the cone opening angle is allowed to vary with distance along the field line. To apply this model to Saturn the direction and

magnitude of the magnetic field at any point must be known. The model of Saturn's magnetic field which is used is based on Voyager magnetometer experiment results⁹. It can be modified to include the effects of a current sheet¹⁰, but the corrections were not of sufficient magnitude to affect the arc modelling results. The discrete nature of the arcs implies that activity takes place along individual magnetic field lines. For Jupiter the active field lines were usually assumed to have magnetic L values¹¹ of \sim 6, as those field lines pass through the orbit of the moon Io which is known to influence the occurrence of radiation. There is no a priori reason to limit L values of the field lines for Saturn.

The frequency of the emission is assumed to be just above the right-hand cutoff frequency ω_R so that right-hand polarized emission escapes the planet. The cutoff frequency is defined as:

$$\omega_{\rm R} = \Omega_{\rm e} [1 + (1 + 4\omega_{\rm pe}^2/\Omega_{\rm e}^2)^{1/2}]/2$$

where $\omega_{\rm pe} \equiv \sqrt{(4\pi Ne^2/m)}$ is the electron plasma frequency, $\Omega_{\rm e} \equiv |eB/mc|$ is the electron gyrofrequency, e, m and N are the electron charge, mass and number density, and B is the magnetic field strength.

The apparent emission sources for the Earth and Jupiter are in underdense plasma regions $(\Omega_e \gg \omega_{pe})$ close to the planets so that ω_R and the emission frequency are very close to the electron gyrofrequency. If we assume that the maximum emission

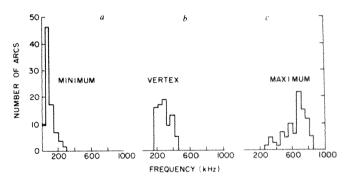

Fig. 2 Histograms of the distribution of the: a, minimum; c, maximum, and b, vertex frequencies in a catalogue of 82 arcs. The catalogue spans 19 June 1980 to 12 December 1980.

frequency in Saturn radiation corresponds to the maximum gyrofrequency above the planetary cloud tops, then the highest emission frequency would be ~1.5 MHz. Observed emission never exceeds 1.2 MHz and is rarely higher than 900 kHz, so there seems to be a fundamental difference from Jupiter. Low L-value field lines have maximum gyrofrequencies in the 900 kHz range, but the lowest gyrofrequencies on these lines are higher than the lowest radiation frequencies so the source region cannot lie on these field lines. Radio occultation measurements of the Saturn ionosphere show that the plasma frequency close to the planet is comparable with the gyrofrequency 12,13. The region where the gyrofrequency is ~900 kHz is several tenths of a Saturn radius above the cloud tops (for $L \sim 5$). In this region the plasma frequency is much less than the gyrofrequency (as it was at Jupiter), suggesting that an underdense plasma environment may again be necessary in the source region. Consequently, the maximum frequency in the models of the Saturn arcs has been determined by assuming the emission occurs only beyond a fixed distance from the planetary cloud tops. This is similar to the Earth's auroral kilometric radiation (AKR) which occurs well above the surface at a distance of ~2 Earth radii¹⁴

The vertex frequency is defined from observations to be a set fraction of the maximum frequency. The minimum arc frequency is difficult to determine since surrounding radiation often mixes with and obscures the low frequency end. The model assumes a fixed lowest frequency at a value determined from observations. The cone angles are allowed to vary with position along the field line from a minimum at the lowest frequency to a maximum at the nose frequency and then back to the minimum

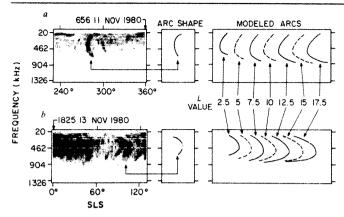

Fig. 3 A comparison of the forms of model arcs to the actual arc shapes derived from the data in Fig. 1. Seven magnetic L values were used to derive the location of seven possible source regions, yielding the arcs shown.

value at the maximum frequency. The formula below is used to vary the cone angle with frequency and is derived from jovian arc studies⁸.

$$\psi(f) = \psi_{\text{max}} \sin\left(\frac{\pi}{2}\right) \left(\frac{f_{\text{max}} - (1 - a)f - af_{\text{v}}}{f_{\text{max}} - f_{\text{v}}}\right) \qquad f \ge f_{\text{v}}$$

$$\psi(f) = \psi_{\text{max}} \sin\left(\frac{\pi}{2}\right) \left[\frac{(1 - a)f + af_{\text{v}} - f_{\text{min}}}{f_{\text{v}} - f_{\text{min}}}\right] \qquad f \le f_{\text{v}}$$

 ψ_{\max} and $\psi(f)$ are the maximum cone angle and the cone angle at frequency f. The minimum, maximum and vertex frequencies are represented by f_{\min} , f_{\max} and f_{ν} and the coefficient a is defined so that $\psi(f) = \psi_{\min}$ at both $f = f_{\max}$ and $f = f_{\min}$.

Arcs from Fig. 1 are compared in Fig. 3 with curves predicted by the arc model. For the vertex-early arcs the model assumes: a cone angle varying from a minimum of 75° to a maximum of 85°; a minimum frequency of 100 kHz; a nose frequency which is 0.6 of the maximum frequency; a minimum distance for the emission region of $0.2 R_s$ above the cloud tops; and the L values indicated. The same assumptions are used for the vertex-late arcs except for the cone angle which varies from 70° to 85° and the minimum frequency which is increased to 150 kHz. These values should not be considered to be unique as the parameters can vary within a small range without significantly altering the fits. Other arcs differ in shape from examples in Fig. 3 but the parameters can be changed to fit those arcs. The curvature of the modelled arcs is sensitive to the difference between the maximum and minimum cone angles; slight changes in this difference have a noticeable effect. The values of the maximum and minimum cone angles can vary by tens of degrees without noticeably affecting the curvature, provided the difference is held constant. Only values of the cone angle of the order of 60° or larger allow the cone of emission to intersect the line of sight of the Voyager spacecraft. This is consistent with the Jupiter emission model in which large cone angles are necessary to explain the 150° separation in longitude between the two major radio sources, which are believed to originate from opposite sides of the same cone.

Constraining the magnetic L value is an important goal. In general, higher L values cause an increased curvature at high frequencies because of the cone beaming geometry. No severe curvature is evident in the observations, which implies that the emission is confined to $L \leq 5$. For Jupiter, the ability to produce good fits assuming a source along the L=6 field line was consistent with the influence of Io on the emission. Four major satellites as well as Saturn's rings are threaded by field lines with L values ≤ 5 . The resolution of the arc fitting process is not sufficient to distinguish whether any of these objects may be affecting the emission.

The source location implied from the above limits agrees reasonably well with the location deduced by Kaiser et al.⁶. That location, however, is confined to a local time region near the noon meridian. For arcs to be formed from hollow conical

beams, the beams must rotate with the planet and so intersect the observer's line of sight. If the source is stationary in local time this is not possible. There may, however, be a limited activity region near the noon meridian in which charged particle precipitation and subsequent radio emission is stimulated along a field line as it rotates into the region, continues as the field line rotates, and then dissipates.

The confinement to a specific local time domain explains the dominance of vertex-early arcs in inbound observations and vertex-late arcs after encounter. Figure 4 displays the proposed emission geometry. Inbound, Voyager 1 approached along a local time line of ~ 13 h. Consequently, the leading edge of the conical beams would usually be the only emission detected. According to the model vertex-early arcs result from the leading edge of a cone, so this is consistent. The outbound trajectory of Voyager 1 was limited to local times around 3 h; thus the trailing edge of the cone was observed and, therefore, vertex-late arcs.

The discrete nature of the arcs for both Jupiter and Saturn remains a problem. For Jupiter, the arcs are discrete but quite regular and usually nested. Saturn arcs appear intermittently

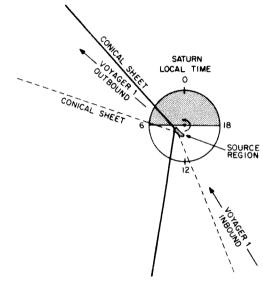

Fig. 4 Hollow conical beam emission from Saturn projected onto the Saturn orbital plane. The source region is confined to the late morning local time sector. Conical emission begins for a particular field line rotating into this region, and ends when the field line rotates out of the region. The directions of the inbound and outbound trajectories are indicated by the arrows. The leading (trailing) edge of the cone rotates through the inbound (outbound) Voyager 1 line of sight.

and are only occasionally nested. Gurnett and Goertz¹⁵ suggested a mechanism for jovian nested arcs which would produce sources along regularly spaced field lines threading Io's plasma torus. Lecacheux *et al.*¹⁶ proposed the production of discrete arcs by a Fresnel screen interference pattern resulting from the observation of the source region through the Io plasma torus. Because there is no similar plasma torus in the magnetosphere of Saturn these theories require modification to explain the discrete Saturn arcs. It may be necessary to look to the solar wind, moons, rings or other influences as sources of discrete excitation.

Our study suggests that the hollow conical emission model of Jupiter arcs can be adapted to fit the Saturn arcs and indicates (1) source regions located along magnetic field lines with $L \lesssim 5$, and (2) a source location several tenths of a Saturn radius above the cloud tops along high latitude field lines. The pre- and postencounter vertex sense of curvature is consistent with conical emission rotating through the late morning local time region.

Saturnian kilometric radiation: statistical properties and beam geometry

M. L. Kaiser*, M. D. Desch* & A. Lecacheux*

* NASA/Goddard Space Flight Center, Laboratory for Extraterrestrial Physics, Greenbelt, Maryland 20771, USA † Observatoire de Paris, Section d'Astrophysique, F-92190 Meudon, France

Analysis of the average properties of Saturn's kilometre wavelength radio emission suggests that the source region is near the noon meridian in the northern auroral zone and/or the polar cusp.

THE detection of kilometre-wavelength radio emissions from Saturn (SKR) increases the possibility that useful comparative radio 'planetology' can be done, to provide insight into the similarities and differences in particle acceleration and precipitation processes on the three known non-thermal radio planets-Earth, Jupiter and Saturn. However, before Saturn's radio emissions can be studied, an adequate description of their average statistical properties is needed. We now present these properties and discuss the implications for source location, beaming, and magnetic surface anomalies. Such statistical properties are already well known for the Earth's auroral kilometric radiation (AKR). Jupiter's decametric wavelength radio emissions have been studied with ground-based instruments for 25 yrs, and space-borne radio telescopes have extended studies of the jovian spectrum to 10 kHz.

The statistical properties of AKR are a strong function of the observer's viewing geometry. Gurnett2 first showed that the observer's sub-spacecraft magnetic latitude and local time were the important coordinates in which to organize studies of the Earth's emission beam properties. The Voyager observations of Jupiter have shown that these same two coordinates are of prime importance over much of that planet's radio spectrum³⁻⁶. Figure 1 shows the magnetic latitude-local time coverage of the three radio planets by the Voyager spacecraft and ground-based observations. For the Earth, >90% of the possible viewing locations have been surveyed frequently enough to provide good statistics; only a small region above the southern polar cap has not been surveyed. For Jupiter, the ground-based observations and the two Voyager fly-bys have covered only $\sim 4\%$ of the possible observing plane, and for Saturn the total coverage will be <0.5% even after both Voyager encounters. This is

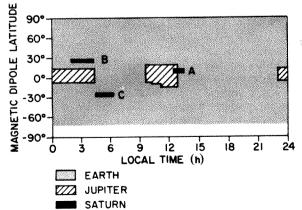

Fig. 1 Positions in the local time-magnetic latitude plane from which radio observations have been made of the Earth, Jupiter and Saturn. Local time is defined as the equatorial plane projection of the observer-planet-sun angle with $12 h = local noon = 0^{\circ}$. A, The inbound trajectories of both voyagers; B, the outbound Voyager 1 trajectory: C, outbound Voyager 2. Thin lines connect A and B, and A and C but they correspond to such brief durations that statistical properties cannot be determined for those viewing locations.

Table 1	Total power o	f SKR	
Occurrence Probability	50%	10%	1%
Inbound power (W) Outbound power (W)	$ \begin{array}{c} 2 \times 10^8 \\ 6 \times 10^7 \end{array} $	$\begin{array}{c} 3 \times 10^9 \\ 1 \times 10^9 \end{array}$	3×10 ¹⁰ 8×10 ⁹

largely due to the near perfect alignment of the Saturnian magnetic moment with the rotational axis⁷⁻⁹ which almost eliminates the 'rocking' in magnetic latitude experienced by both the Earth and Jupiter. We describe the average properties of SKR as observed from locations A and B in Fig. 1 by the Voyager 1 planetary radio astronomy (PRA) instrument 10,111 for a 2-month period centred on the 12 November 1980 encounter. Location A specifies the inbound (pre-encounter) geometry (at ~12.5 LT and +8° lat) and location B, the outbound (postencounter) geometry (at ~3.5 LT and +26°). Location C will be the Voyager 2 outbound trajectory in late 1981. The Saturn hemisphere from 13 to 01 h is only briefly entered by the Voyagers, specifically during their fast swing-bys at closest approach. Additional radio noise from a source in this region would not be detected by the Voyagers.

Occurrence probability

An analysis of the occurrence pattern of SKR as a function of Saturn's rotation phase has shown 12 that SKR occurrence is not continuous, but variable and roughly periodic. From preencounter observations, a Saturn longitude system12 (SLS) can be defined. SKR was found to be well organized in longitude with an occurrence rate maximum near 90° and a minimum at ~270° in sub-Voyager SLS. The PRA observations near closest approach 13 showed that the SKR occurrence pattern was fixed relative to the Sun with maximum occurrence rate near 100° in sub-solar SLS.

Figure 2 shows the absolute occurrence rate of SKR bursts stronger than 10^6 Jy (1 Jy = 10^{-26} W M $^{-2}$ Hz $^{-1}$) as a function not only of sub-solar SLS, but also of observing frequency. (We have adopted 1 AU as a 'standard' distance for normalizing flux density measurements.) The reported13 similarity in the occurrence patterns for both the inbound and outbound trajectories is clear. However, the absolute occurrence rate for the outbound observations is roughly half that of the inbound observations. Furthermore, the maximization of occurrence in the 100-200 kHz frequency range which is so evident in the inbound panel is replaced in the outbound panel with a broad maximum from 100 to 500 kHz. At the 5% occurrence level, SKR extends from ~ 40 to 600 kHz. SKR events extending to 1,200 kHz have been reported¹³, but the occurrence rate of these events (>10⁶ Jy) is «1%, with no discernable difference between inbound and outbound observations. SKR events as low as 3 kHz have also been reported14

Figure 3 shows, for an observing frequency of 174 kHz, the probability of detecting emission above a given flux level for both inbound and outbound trajectories. The probability of

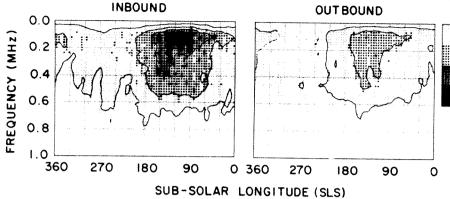

Fig. 2 The absolute occurrence rate of SKR above 10⁶ Jy is shown as a function of sub-polar SLS and observing frequency for the Voyager 1 inbound and outbound observing positions (corresponding to A and B in Fig. 1).

detecting a given flux density event is generally higher on the inbound leg than outbound. For example, the probability of detecting SKR stronger than 10^5 Jy is $\sim 58\%$ inbound, but only 32% outbound. For events stronger than 10^6 Jy, the probabilities are 18% inbound, and only 8% outbound.

Several authors^{12,13} have reported that SKR is largely right-hand (RH) polarized with left-hand (LH) SKR detected only during the approximately 2-month period immediately preceding encounter, and not at all after encounter. Figure 3 shows the occurrence probability of LH SKR. Its rate of occurrence is only a small fraction of the total SKR occurrence rate. The distribution of LH SKR in frequency and SLS is not well determined due to the sparsity of data, but there is evidence that the LH emission maximizes near 350 kHz at about 300 ° SLS. This is ~200 kHz higher in frequency and 180 ° displaced in longitude from the RH polarized emission observed inbound.

Power flux density

Figure 4 shows the average power flux density spectra of SKR at three different occurrence levels for both the inbound and outbound observations. The spectra have been averaged over all longitudes. The general trends evidenced in the occurrence probability distributions (Figs 2 and 3) can be seen. The flux densities observed during the outbound trajectory are lower at frequencies below 500 kHz than the corresponding values inbound. The equivalent isotropic powers for the three occurrence levels are shown in Table 1. Roughly three to four times as much power is received at observing position A than at B.

The frequency of peak flux for inbound observations is near 150-175 kHz. The peak outbound appears to be shifted to higher frequencies, in some cases as high as 400 kHz. However, comparison of the ratio of the corresponding inbound and outbound spectra reveals that this apparent shift towards higher frequencies is caused by a systematic decrease in observed intensities at lower frequencies for outbound observations. For example, for the 10% occurrence spectra, the received flux at 100 kHz is five times larger for the inbound case than for outbound. This ratio decreases to a factor of 2.5 at 250 kHz and approximately equal levels are observed at or above 500 kHz.

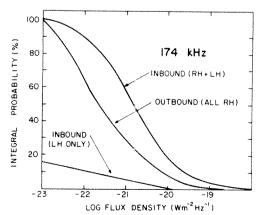

Fig. 3 The occurrence probability of SKR above a given flux level for a particular observing frequency for inbound, outbound and LH polarized events. The flux densities are normalized to a standard distance of 1.0 AU.

Discussion

The statistical SKR properties discussed above strongly constrain possible source locations. We know that SKR emanates from a source which is fixed relative to the Sun, perhaps much like the Earth's AKR. However, SKR would need to be emitted into an extremely sharp beam for the very small magnetic dipole tilt to account for the very large (more than a factor of 100) intensity modulation as a function of rotation¹³. Instead, we favour the concept that emission is generated when a particular longitude arrives at a particular solar hour angle (local time). From the flux level differences inbound and outbound, the radio beam is clearly oriented more towards the inbound trajectory. This is reinforced by the fact that the low frequency portion of each outbound SKR spectrum is depressed. Studies of the Earth's AKR angular distribution¹⁴ show that high frequencies

5%

20 %

35 %

50 %

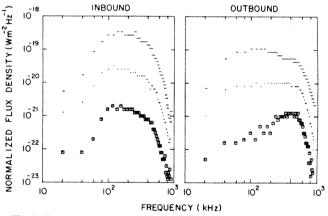

Fig. 4 Typical SKR flux density spectra observed 50% (□), 10% (•) and only 1% (bars) of the time are shown for inbound and outbound observations.

are beamed over a much wider angle than low frequencies due to refraction. If analogy with AKR is correct, a beam oriented more towards the inbound trajectory would tend to illuminate the outbound trajectory at high frequencies, but perhaps not at low frequencies.

From consideration of the inbound spacecraft trajectory and the polarization of SKR, Warwick et al. ¹³ concluded that the RH emission is emitted in the magnetoionic extraordinary mode from the northern hemisphere, and the LH emission is most likely from the southern hemisphere. This implies that SKR is most likely generated near the electron gyrofrequency in the source region. The magnetic field model ⁷⁻⁹, coupled with the observed SKR frequency range, $<20-\sim1200$ kHz, suggests that the emission source region is confined to field lines exiting the planet at rather high latitudes, probably >60°. At lower latitudes (<56°) the gyrofrequency does not extend as low as 20 kHz anywhere on the field line.

Additionally, because the SKR comes from a source fixed in local time, the observation¹³ that the sense of polarization remains RH inbound and outbound implies that both trajectories are illuminated by the forward lobe of the same beam. In other words, the initial wave direction must be predominantly

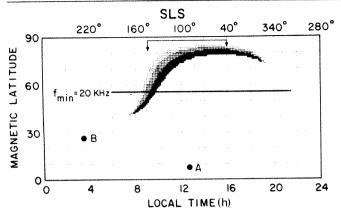

Fig. 5 The shaded region shows, in the saturnian local time-magnetic latitude plane, the locus of possible emission cone axes for frequencies near 175 kHz. The dark shading is for an assumed $\cos^{1/2} \theta$ beam pattern where θ is the angle between the ray and field line, the moderate shading for a $\cos \theta$ pattern, and the lightest shading for a $\cos^2 \theta$ pattern. Also shown is a line which corresponds to an equatorial electron gyrofrequency of 20 kHz. Only regions at higher latitudes than those indicated will have emission as low or lower than 20 kHz. The bracketed arrows show the region where similar plots for 20 kHz and 500 KHz intersect this plot. Because the SKR beam appears to be fixed in local time, we can approximately equate longitudes to local time and this scale is shown at the top . A similar analysis done with the cone axis parallel to the field gradient direction gave essentially the same result.
